**Hardening Plants.**—Zonal Pelargoniums being grown in cool houses and pits, and well exposed to the full sunshine, require but little hardening off; in fact, ought now to withstand any cold weather we may now have. Those recently growing in heat will still need a little protection during cold frosty nights, and this protection will be still more effective if it also ward off heavy rains. The last to be fully exposed and planted out are such easily injured kinds as Heliotropes, Iresines, Coleuses, Alternantheras, and the majority of the sub-tropical plants. Iresines and Coleus may yet be struck, and now is a good time to put in large quantities of Alternanthera cuttings. A nearly spent hotbed or a slight newly made hotbed faced over with a layer of fine sandy soil about 4 inches deep is the best place for striking them in quantity. The cuttings may be dibbled into this 3 inches apart each way, and if kept close and shaded from bright sunshine will strike root quickly and be quite as large as required by bedding-out time. In hardening off these and other delicate plants the greatest care must be taken to avoid over-watering and to prevent saturation by heavy rains. If injured at the roots they are a long time before they recover. If the stock of Iresine Herbstii is insufficient, a good substitute will be found in Amaranthus melancholicus ruber. Sown in heat at once it will germinate in a few days, and potted off singly into 2-inch pots will, if kept in heat, be large enough to bed out by the second week in June.

**Sowing Carnation Seed.**—No plants in the borders are more useful than these and Picotees, and seedlings are by far the most vigorous and floriferous. It is true a good percentage of them may be single-flowering, but even these find plenty of admirers. The seed should be sown thinly in pans or boxes of fine sandy soil and only lightly covered. If well attended in the shape of proper moistenings and shading, the seed will germinate in a cold frame or under a handlight, and still more quickly in a gentle heat, such as a partially spent hotbed. We sow very thinly, and this saves the trouble of pricking out, the plants being transferred to a well-prepared bed directly they are large enough to stand the exposure. If sown at all thickly they must first be pricked off in boxes or pans of light sandy soil, and later on planted out. They succeed best in slightly raised beds, say about 6 feet wide. Our last summer's seedlings were planted out 12 inches apart each way, and the young flower growth meet all round. So very floriferous are they, that we find it unwise to depend upon them a second year, and annually raise a fresh batch.

**Campanulas.**—Those of the Medium or pyramidalis type are the best for the open borders, these being quite hardy in most districts and flower profusely late in May and June. They also put up well from the open ground, and are then very serviceable for conservatory decoration. The seed ought now to be sown on the even surface of a pan of fine soil and only lightly covered. It may be stood in a warm frame or in the open, shading from sunshine, and moistening when necessary. If the pan is covered with a square of glass germination will be quicker and more sure. When the seedlings are large enough to handle, prick off the required number in pans or boxes of good soil, and finally plant out when of good size, disposing them about 18 inches apart each way.

**Stocks, Wallflowers, and Sweet Williams.**—It is unwise to delay sowing these till after the busy hedding-out time is past. To have them strong and bushy before the winter the seed ought to be sown early or some time in May. If the ordinary garden soil is light the seed may well be sown thinly, either broadcast and covered with a little fine soil, or in shallow drills about 6 inches apart. Where, however, the garden soil is heavy and cold, and slugs perhaps very abundant, it will be found the best plan to sow the seed either in boxes or under handlights, using a little light sandy soil in each instance. In this way nearly every seed will germinate, and later on the young plants may be pricked out in a sunny, open position, where they are to flower, or they can be transplanted. The Brompton and Queen Stocks are suitable for present sowing, these withstanding an ordinarily severe winter, and flowering grandly in the spring. Wallflowers Blood Red and Belvoir Castle Yellow, or the best procurable dark red and yellow strains, may be substituted, and those who may wish to try the tall double German Wallflowers should sow these now. Most seedsmen have a good strain of Sweet William.

**Pansies, Polyanthes, Primroses, and Alpine Auriculas.**—All these can be readily increased from seed, although they ought to have been sown in March or April, in order in each case to have strong flowering plants for next spring. Sow in pans of fine sandy soil, keep close and shaded, and directly the seedlings appear give more air and gradually expose to the light. Prick off the seedlings when large enough to handle, and transplant to well-prepared sheltered beds directly the plants are strong enough to bear removal.

**Carpet Beds.**—Where the beds intended to be filled with carpeting plants in various designs are unoccupied with spring-flowering plants,

advantage should be taken of showery weather to commence filling them. The groundwork of the plan is generally filled in with Sedums, Veronica repens, Antennaria, Mentha, Herniaria, and other dwarf and hardy trailing plants, and these may be, and are, all the better for being freely divided and dibbled in thinly and evenly. Every little piece will grow providing it is kept slightly shaded with branches of evergreens and watered frequently till well established. It is unwise to attempt to lay down any complicated design, as these, although effective on paper, are often failures when worked out, and the more simple designs, these having every figure quite distinct, are more easily planted, and are less trouble to keep in order. The lines of the design should be traced out on a perfectly smooth and fine surface, and may be made more distinct if formed with silver sand. The groundwork being filled in with the above-named plants, only leaves the figures to be filled with the Alternantheras and other choice plants when this may safely be done.

## THE BEE-KEEPER.

### INITIATORY INSTRUCTIONS.—No. 6.

I HAVE endeavoured to lay before intending bee-keepers the fundamental rules of profitable bee-keeping in a plain and concise manner, and I am sure success will follow those who abide by the instructions given, and so long as their hives do not exceed the number the bee-keeper desires to work for profit. Whenever their hives exceed that number, experiment with these in every conceivable fashion to get at facts, and be able to rely upon your own knowledge and method of working, without which no one will ever be a successful bee-keeper.

Spreading brood will no doubt be included in these experiments, but the bee-keeper possessing a good understanding will soon discover its futility. A young fertile queen, new combs, plenty of bees and well provisioned, are the natural essentials toward strong hives, early swarms, and profitable bee-keeping, if right-shaped and full-sized hives are used. If hives are to be useful and handy for carrying about, getting the advantage of flowers in different districts, the frames of such hives must be made so that they will retain their natural position (which is 1½ inch from centre to centre) in a rigid manner. This will preclude the possibility of making even a more foolish manipulation than spreading brood—viz., that of bringing the combs nearer each other than Nature has designed, allowing at least two bodies of bees between the seams necessary to keep up the proper degree of heat, and attend to the brood in a proper manner, which is impossible when the distance between the combs is reduced to a quarter of an inch or so. While I am writing this (May 4th), we have not had a week's fine weather—most unsuitable for manipulating bees; yet I hear of some well-managed hives are within a week of swarming.

Is the present year an exceptional one? Yes, so far as the long continuation of a very low temperature is concerned, but not otherwise. The weather in other respects is just as we have hitherto experienced, and just as one hour of frost will kill a tender plant, so will one cold day in April or May destroy the spread brood of any hive when the bees draw together to preserve themselves and brood alike during the cold. March, April, and May are the three severest months for bees, and during these months they are rapidly preparing for swarming, and should not be exposed in any way.

There is one experiment that I have tried with success, and would like to see others give it a fair trial. It is lining the inside of the hive with sheets of wax, so that the wood will not absorb moisture. This is in direct opposition to the opinions and plans of many who seek an absorbing material for the inner walls of hives—good when these are thin and single-walled, but bad when thick and double-cased. With the former, when covered with straw, the heat of the hive forces it outward and the current carries it away; but in the latter case the walls absorb moisture, returning it to the hive, while there is no possible escape for it otherwise, and there is no greater enemy to bees than damp, especially on floors and in the corners of wide hives. Wax is the natural non-

conducting product of the bees, which they build their combs, therefore it is the best thing that can be used, being comfortable for the bees to walk on, does not absorb damp, and, if a hive is infected with foul brood, only requires to be removed by heat and lined anew. All the condensed vapour falls through the ventilating floor and the hive is in the best possible condition for health and comfort to the bees, preserving them throughout the year satisfactorily, and this is the best and only way of having the proverbial strong hives of bees which are able to collect abundant stores for their master and themselves.

Providing bees with water in a proper way is of greater importance, and saves more bees' lives than many bee-keepers are aware of. If bees are allowed to find water from natural sources many are lost, falling into water, or, what is more common, many die in the act of sipping it from places so cold that the bees become chilled. To overcome this some means should be devised to supply the bees with water, so that the sun will heat it. As the majority of bee-keepers incline to combine the useful with the interesting and ornamental, the ornamental crystal fountain as invented by "A Renfrewshire Bee-keeper" cannot be surpassed. When once the bees find it, it prevents them leaving the apiary in search of water, and it whenever the sun shines become heated and tempting to the bees.

In preserving bees lies the secret of success. In addition to what has been said on that subject, endeavour to keep down every scent of honey, syrup, or combs that is likely to attract bees, which incites robbers and may spread disease. Hives with common floors turn out all the *débris* from the entrance, which attracts stranger bees, and causes fighting and spreads disease. The ventilating floor prevents that if the *débris* is collected on a piece of paper and burned.

The temporary covering of hives both at home and on the moors so as to completely throw the water off is sometimes not properly performed. Those who are in the habit of sending their bees to the Heather will find the single-cased hive handiest and superior in every respect; a mat wrapped around them and plenty of dried grass above, placed in an uneven manner so as to allow the air to pass beneath an oil cover or sheet of metal, not tied with cards, but weighted with stones put into pockets, which may be either sewn or fastened with hooks. After September neither alter the appearance nor site of any hive unless it be some miles distant, and even then preserve the original appearance of the hive, and on every occasion of removal. Never place hives in a line nor equi-distant from each other. Bees have their peculiarities not easily explained. They are retentive in memory, yet a slight alteration misleads them. This season my hives stood in twos, a high hive and a low one together, and on each side were low ones. In one of these spaces I placed a similar high hive, and although it was 6 feet distant from the tenanted high one, it attracted its bees in great numbers, so we had to remove it.

Some things are inexplicable. The memorable bad honey year of 1877 will be long remembered as one of the many poor seasons for honey. Towards the end of July of that year, when I left on Monday for the Edinburgh Show, I left between twenty and thirty of the strongest-bred Ligurian hives I have ever seen, and on returning on Saturday found them all in a state of starvation, saved only from death by the timely feeding by my wife, who detected their state in time. There was no alternative now but to feed. To every one I gave from 25 to 30 lbs. of sugar within a week, hoping this would be sufficient to tide them over till another year, which, with the exception of one, nearly sufficed. The one referred to excelled every other hive in numbers, which I examined after I had given it 25 lbs. of sugar, but not a single cell of syrup was to be seen. What they did with it and where it went to I do not know, except that the bees took it in the first instance, but to what use they put it I know not. It got another 25 lbs. (50 lbs. altogether), but this time it stored and sealed it properly.

I note the remarks made by "Felix" in his closing paragraph, page 323. I quite agree with what he says. I think my life would have been ill spent if bees and appliances for their management had been the only good I had done. Praise I neither want or like, but I certainly dislike to see those who have been bee-keepers only a few years or removed from the original system of bee-keeping pirating and appropriating others' ideas.

With the Editor's permission I may some day give the dates of inventions, with inventors' name, of many of the appliances in use at the present time.

Perhaps the most important instructions I can give to beginners is to be careful and get the best-made appliances from those with most experience.—A LANARKSHIRE BEE-KEEPER.

### SEASONABLE JOTTINGS.

THOSE bee-keepers who made proper preparations in the autumn to insure this year's success will now be rejoiced to see their bees busily engaged in supers, divisional or sectional, for no others ought to be employed unless there is a special local demand for them. A late spring has retarded blossoms, while bees do not appear to be many days later than in milder seasons. Last year my stocks were supered on the 25th April; this year supers were placed on the 26th, or one day later. All supers were at once taken possession of by the bees, and are now being worked most satisfactorily. Honey is coming in principally from Gooseberries and Currants, but Apples, Pears, Cherries, and Plums are all bursting into bloom, so that in a few days a vast field of labour will be extended before the bees. If the weather continues fine and not so hot and dry as to parch up vegetation the prospect for bee-keepers is a glorious one. The late blossoming of the orchards will enable the bees to gather honey in greater quantity than is usually the case, the season being extended over May until white Clover bursts into bloom by Sycamore, than which there is no more honey-giving tree nor any more welcome, yielding its rich nectar as it does just when otherwise an ugly hiatus would occur between the ingathering from the fruit and Clover bloom.

Most bee-keepers will by this time have decided whether to work for run or comb honey. In the present state of the honey market the most advisable method is, I think, to get all in the comb if possible, taking care to employ supers of the kind which are most readily saleable and command the highest price.

Those who employ sectional supers and sections in particular seem occasionally to experience no little trouble in fixing foundation firmly in them. There is a small machine by which foundation is said to be readily and neatly fixed, but as I have never had occasion to employ any such mechanical aid in so simple a matter I cannot say anything of its merits or demerits. It is not a necessity, and should therefore be scheduled with the many other useless and expensive because not necessary appliances. It may be a help to some if I point out a simple, easy, and very speedy method by which foundation may be fixed in sections, either whole sheets or starters only being used.

The foundation being cut into pieces of the desired size, take the section and hold it top downwards in the left hand, taking care to leave the thumb free for supporting the sheet. Now, the piece of foundation must be taken in the right hand, and the edge which is to be fastened to the section held to a fire until it becomes a little, but very little, soft and pliable, then lay it flat along the bottom of the section, such bottom being in reality the top when the section is in its proper position, and with the thumb of the right hand press the tiniest strip of the edge of the wax to the centre of the bottom piece of the section until the wax begins to harden, when the thumb of the left hand must raise the foundation until it stands at right angles to the bottom. The section may immediately be placed in its natural position, and if the work has been done properly no fear need be entertained of failure. By this plan no extra wax is used, no material wasted, and the sheet is thinned down at the junction, this being a good feature in the method. It is very easy when a little experience in the work has been gained to fix 100 an hour. It is difficult to give instructions so plain in such a matter as to enable all to grasp the details, but the general idea will be made sufficiently clear perhaps to enable those who desire to do so to attach their foundation more firmly and more easily than before.

Queen wasps are more numerous this year than for many seasons, and unless either heavy rains or some other destructive agent destroys these pests, weak stocks will have to fight in autumn for their homes and stores. They can easily be destroyed, although it seems a pity to kill the bright gleaming insects that shine so prettily in the green verdure, but they must die or the bees will suffer.

The question of vessels for our honey will soon again become

an urgent one, and demand the attention of all. At present there appears to be nothing superior to plain glass jars, and it is always well at any rate not to appear to charge anything for the glass, the extra price can be put on the honey. People appear to prefer to give 1s. a pound for a pound glass of honey rather than 11d. for the honey and 1d. for the glass. Each one must look to his own customers and suit their varied wants and requirements. Pretty vases please some, plain jars are fancied by others; cheap, clean and clear glass of any description is my favourite honey jar, neatly, yet unpretentiously, labelled "pure honey," and tightly sealed. All jars should be made returnable to home customers; a fair commission be given to those who undertake to sell on these terms, and as much honey as they require for home use free; the best quality always being supplied, no inferior being allowed to leave the apiary. Swarms this year will, in neglected apiaries, be later than usual, few stocks now being strong enough to give much prospect of a May increase.

The season is now before us; the future, with all its uncertainties, failures, and successes, lies hidden from our view. I can only hope that each one may realise how profitable bee-keeping is when proper attention is paid to details of management, and how great the pleasure in supplying the wants and forestalling the desires of bees, helping, assisting, and watching them as they labour in a ceaseless effort to provide for the storms of a yet distant winter.—FELIX.

### SECTIONS OF HONEYCOMB FROM A FRAME HIVE.

I SHOULD be grateful for information on the following points, in connection with bee-keeping, through the columns of your valuable paper. I have a bar-frame hive capable of taking sixteen standard size frames parallel with the entrance, into which I propose putting a swarm as soon as I obtain one. What would be the best way to manage the hive in order to obtain the best yield of honey in 1 lb. sections, and to leave the bees sufficient stores for winter? And which is the best way to fix foundation in sections? What would be the simplest and most expeditious way of extracting from twelve to eighteen frames of honey, so that the combs may be used again? It scarcely seems necessary to purchase an extractor for so small a quantity. Does Mr. Thomson's "Essay on Bees" contain a description of the Stewarton hive and the mode of working it? Where is Pettigrew's "Handy Book of Bees" published? The last edition of "Manual for the Many, Bee-keeping" being, I am informed, out of print, will another edition be produced; and, if so, when will it be ready?—F. E. B.

[It depends altogether on circumstances how your hive should be managed to obtain the best yield of honeycomb; time, size of swarm, and locality are all potent factors. But, supposing all things are favourable, then your hive should be nearly filled with comb (in all its sixteen frames) before any sections are put on. If one swarm is not sufficient for this in time for the honey season, two swarms should be joined. Then put your sections on the top, half covering the top at first only, and as soon as these are well begun add more, continuing adding empty ones and removing full ones as the season advances. The form of your hive is not the proper one for obtaining surplus honey, and the frames parallel to the entrance is not a point of good bee husbandry. The sixteen frames are all required for breeding and storing honey for the future wants of the bees; it would be better a little larger. If you would adopt the tiering system advocated by "A Renfrewshire Bee-keeper" and others in this Journal for the past thirty years, and now universally adopted by those who opposed it as well as nearly all others, you would find it more to your profit and to the comfort of the bees. The best way to fix comb foundation in sections is to have them grooved, then with a teaspoon that has been left in the wax while melting in a glue pot, pour a little wax, so that it will keep in the groove, first on one side then on the other, holding the section a little elevated, so that the wax will pass over the whole length of frame or section.

When honey is not very thick, by carefully uncapping the cells and placing them flatways on a sieve, the honey will drip out; but the process is a slow one and deteriorates the quality of the honey. When honey is thick nothing but a presser will force it out. This was the case last year. The centrifugal extractor was of no use even for our Clover honey. There is a description of a cheap honey extractor in the *Journal of Horticulture*, which appeared some twenty years ago, similar to the "Mepel" G. O. Wray claims to have invented; but if you wish to be at little or no expense, why not try the original extractor, put the combs in a can with a handle, and swing round your head until the honey is ejected?

The Essay contains a description and the management of the Stewarton hive. Pettigrew's "Handy Book on Bees" may be had from Blackwood and Sons, Edinburgh. The manual on bee-keeping will be reprinted and will be advertised when ready.]

### TRADE CATALOGUES RECEIVED.

James Veitch & Sons, Chelsea.—*Catalogues of New Plants for 1886 (illustrated) and Bedding Plants.*

E. G. Henderson & Son, Maida Vale, W.—*Catalogue of New, Rare, and Other Plants.*

James Dickson & Sons, Newton Nurseries, Chester.—*Catalogue of Stove, Greenhouse, and Conservatory Plants; List of New Roses, &c.*

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Waterproofing Calico (Elbor).**—A cheap and easy mode of rendering calico waterproof, so as to make it applicable as a temporary substitute for glass as a covering to frames, is by the following process:—Take pale linseed oil three pints, sugar of lead 1 oz., and white rosin 4 ozs.; grind the sugar of lead with a little of the oil, then add the rest and the rosin. Stir the whole well together in a large iron pot over a gentle fire. Tack the calico loosely on the frame, and apply the mixture while hot with a large brush.

**Captain Christy Rose (C. E. Smith).**—Some kinds of Roses are more apt than others to produce blooms such as the one you have sent to us. It is due in many instances to the unripened state of the wood. Poverty of the soil will also bring about the same result. A check from some cause or other will bring about the production of green-eyed monsters. Another and a certain cause is unduly forcing them into bloom before they have time to thoroughly develop themselves. But in most cases it is either due to poverty of the soil or inactivity of the roots.

**Liquid Manure for Fruit Trees, &c. (F. J.).**—The best kind of liquid manure you can make to use "stiff" for diluting with water is soot. Place two bushels of soot in a cask and add thirty-two gallons of water. Stir well with a broom handle, or an old worn-out birch broom is best, and repeat until the soot is thoroughly mixed. A pint of the stuff so formed may be added to three gallons of water for watering fruit trees, Strawberries, &c. The whole must be well stirred up before use. Guano may be used at the rate of an ounce to a gallon of water, and it only needs placing in the water and stirring up when used.

**Warts on Vine Leaves (J. S.).**—The warts or excrescences on the under side of the Vine leaves are caused by a check to the evaporation from the foliage and consequent stagnation, followed by a period in which the evaporation is excessive and the tissues are ruptured, hence the excrescences appear. It is usually most prevalent in dull seasons, when air cannot well be admitted without lowering the temperature. In dull and cold periods a little extra fire heat should be afforded so as to allow of air being given to induce a circulation, and this without lowering the temperature. The warts are not so numerous as to injure the Vines, and have nothing to do with phylloxera.

**Strawberry Blossoms without Anthers (J. E.).**—The usual cause of the blossoms not having anthers is a deficiency of moisture in the previous growing season, which prevents the proper development of the buds. Lack of anthers sometimes arises from excessive luxuriance in the plants, and in that case the embryo flowers are not properly formed, being in that condition known as not "thoroughly ripened." In your case we think it is due to the drought of last season, and the supplies given between the rows have induced a late growth. The loss of anthers is sometimes due to cold. With finer weather the late blossoms will probably come quite right, and the blossoms without anthers may set through pollen reaching the stigmas from other blossoms.

**Worms in Lawns (D. Watson).**—Either of the following two methods may be tried; both have answered the purpose of extirpating worms:—1, Half an ounce of corrosive sublimate (bichloride of mercury) dissolved in fifteen gallons of water will cause worms to come to the surface; but care must be taken that fowls do not eat them, otherwise they will be poisoned. A peck of freshly made quicklime mixed with forty gallons of water, and allowed to stand till it clears, if applied through the rose of a watering-pot will have the same effect. These mixtures may also be used to remove worms from flower pots. 2, Place a peck of quicklime in thirty gallons of water, stir well up, and allow it to stand for a few days until it is quite clear; then water the lawn thoroughly with the clear lime water. The worms will come to the surface, when they may be swept up and cleared away. This is an old and useful mode of eradication.

**Buckland Sweetwater Vine (Clifton).**—This Grape is generally very shy even under good cultivation, and often fails to carry a crop when grown by the most skilful cultivators. If you desire a white Grape you cannot do better than procure a Vine or two of Foster's Seedling, which is a free and certain fruiter, and will do well with the same treatment as Black Hamburgh. If inarched at the base this season, and the old rods cut off at pruning time, they would make strong canes another year. If you decide, however, to fill the space with Black Hamburgs you may commence doing so at once by encouraging shoots to extend from the base. Some of the lower laterals could be removed to give them light. You will save time by

this system, and next year you will have canes that will furnish a third at least of the space. We have often known the Buckland Sweetwater bear well on a strong well-ripened young rod when scarcely any bunches were produced on spurs after close pruning.

**Tobacco-leaved Cherry** (*C. Morden*).—Certainly there is a Cherry distinguished by the above name, and with half a dozen synonyms in addition. There is nothing for which this Cherry is remarkable, except its large leaves and high-sounding name; however it came to be called "Four-to-the-Pound" would puzzle anyone to imagine, but such is the name by which it was at one time known, and under which it was found in all nurserymen's catalogues. It is a very old Cherry, and is evidently of English origin, being mentioned by Parkinson as early as 1629, under the more modest designation of "Ounce Cherrie." He says, "The Ounce Cherrie hath the greatest and broadest leafe of any other Cherrie, but beareth the smallest store of Cherries everie yeare that any doth, and yet blossometh well; the fruit also is nothing answerable to the name, being not great, of a pale yellowish red, neere the colour of amber, and therefore some have called it the Amber Cherrie." There is no doubt it is this variety also which is described by Meager under the name of "Olliegeberrylin," which he says is "as big as an indifferent Apple." The Germans ascribe its introduction on the Continent to the Earl of Murray, who had a seat at Menin, in Flanders, whence it was taken into Germany by M. Seebach, colonel of an Austrian regiment of cavalry, and who received it from Lord Murray's gardener under the name of Quatre à la Livre. The leaves are a foot, and sometimes 18 inches long.

**Berberis vulgaris** (*D. P., Lancaster*).—As you appear to be particularly interested in the Barberry, the following will perhaps in some measure meet your wishes, but we cannot undertake to "tell all about it," especially in the form of a reply. It is a native of the East, and is noticed by the earliest Arabian writers as the Berberys. This was accepted by Linnæus for the generic name. The specific name, vulgaris, common, needs no explanation. Bauhin says its English name was Piridge, and we know that Pirige was the Anglo-Saxon for a Pear tree. But Gerard and others of our early herbalists say it was called the Piperidge, or Piperidge tree, and this may have been derived from the Norman, for Pepin is a pip, and rouge, red. Parkinson, writing later, says, "Many others do call it Berberis, and so the generall vote goeth now-a-days." The flowers are offensive to the smell when near, but at a short distance their fragrance is extremely fine. The fruit is of a most agreeable acid flavour, cooling, and good to quench thirst in fevers, and, boiled with sugar, makes an excellent preserve. The berries are also used as a dry sweetmeat in sugar plums, and the juice to flavour sugar comfits; they are cooling, astringent, and antiscorbutic, and are said to be of great use in bilious affections, diarrhoea, and all cases where heat and acrimony prevail. Though used formerly, and highly spoken of by some old physicians as performing marvellous cures, they are now entirely expelled from modern practice, it having been found that any medicinal uses which existed in the acid of the Berberry were equally met with in other fruits, and hence the Currant is the only one which has been retained in the pharmacopœas. The bark of the root and inner bark of the stem afford a colour which will dye linen or cotton a fine yellow, with the assistance of alum. In Poland they dye leather of a most beautiful yellow colour with the bark of the root, and it is said to be from this root that the fine yellow of morocco leather is obtained. This colouring property is owing to a peculiar crystallisable principle, which has been named Berberin; and which is said, in a dose of from one to ten grains, to be tonic and purgative. This principle has been ascertained to possess alkaline properties. The bark of the Berberry, taken as a decoction in ale or white wine, is said to be purgative, and to have proved highly efficacious in the cure of jaundice; hence, in some parts of the country, we have heard the plant called the Jaundice Berry. A popular opinion exists throughout Europe that the Berberry should never be allowed to grow in proximity to Wheat, from the power it has of communicating blight to the plant and rendering the ears abortive. A singular circumstance is observable in the stamens of the Berberries, and particularly that of the common Berberry. They are all bent back to each petal, the concave tips of which shelter the anthers. No agitation whatever of the branch will have any effect on them; but if the inside of the filaments be merely touched with a small bit of stick, a pin, or a needle, they instantly spring from the petals, and shake the pollen against the stigma. This irritability does not exist on the outside of the filaments, nor in the anthers; and if the stamen is bent towards the stigma by the anthers only, no such action is exhibited. From this it is evident that the sudden spring of the stamens is owing to a high degree of irritability in the side of the filament next the ovary, by which, when touched, it contracts, that side becomes shorter than the other, and, consequently, the filament is bent towards the ovary. This irritability is perceptible in the filaments of flowers of all ages. If the ovary is cut off, the filaments will still contract, and, nothing being in their way, will bend quite over to the opposite side of the flower. After irritation the stamens will return to their original place, and, on being touched again, they will contract with the same facility as at first. These anthers bent back and sheltered from rain in the concavity of the petals, would probably never reach the stigma, and thereby propagate the species, were it not for this wonderful irritability; there they remain till some insect, coming to extract honey from the base of the flower, thrusts itself between the filaments, and, almost unavoidably, touches them in their most irritable part: the anthers rise and distribute the pollen on the stigma, and thus impregnation of the ovary is accomplished.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*F. C. Weavers*).—2, *Kerria japonica* flore pleno; 4, *Resembles Pelargonium graveolens*; 5, *Phyllocactus Jenkinsonii*. The others were not recognisable. (*W.*).—The shoot with two or three leaves is quite insufficient for identification. (*B. J. B.*).—*Viburnum Lantana*, the Wayfaring Tree. (*J. Gilbert*).—*Prunus Padus*, the Bird Cherry. (*Y. R.*).—1, *Spiraea prunifolia* flore pleno 2, *Prunus Padus*; 3, *Berberis Darwinii*.

## COVENT GARDEN MARKET.—MAY 12TH.

TRADE improving, and with good supplies prices remain easier, Strawberries alone maintaining their advance.

## THE FUTURE OF FARMING.

FERTILITY well sustained in soil that is clean, well drained, well divided by fine stones or suitable substitutes, must be regarded as an indispensable fundamental point in the future of farming. How best to impart fertility to the soil is a matter to which more and more attention is being given. Economy with efficiency is a combination to which our best efforts must be given; we must know what elements of plant food are required in the soil, and also how we can supply the want. It is true enough that farmyard manure contains all the elements of fertility required to store the soil with nutriment, but having regard to the cost of its manufacture and use, we are bound to inquire if we cannot in some measure avoid this heavy outlay. Think what it involves—cattle, yards, litter, food, attendance, the risk of

losses, besides the subsequent heavy labour of removal and distribution with men, horses, and carts. Do not the numerous experiments with chemical manures by the Royal Agricultural Society and other associations all point to a recognition of the common want of portable, cheap, efficient fertilisers? Yet efforts to ascertain and to show unmistakably which are the best manures for our purpose meet with opposition both active and passive—active from interested dealers in special manure mixtures, and—strange to say—passive from very many of the class they are specially intended to benefit—the farmers. This is a matter to which, however, success is quite certain to attract attention and respect, and eventually to obtain full and ample recognition. Let those who lag behind and clog the wheels of useful progress learn as they must do how unmistakably they are being left behind in the race, and they will, simply because they must, bow to the inevitable, and adopt the ways and means so generously placed at their disposal by those whom they once regarded with suspicion and doubt.

The soil as a medium for conveying food to plants, and as a substance in which the roots of plants grow, spread, and cling to, must have more thoughtful intelligent attention. The nonsensical notion that soil requires periodical seasons of rest must be got rid of as being altogether fallacious. There must be no more long fallows in the ordinary course of farming; there never has been any good reason for them excepting only after two or three consecutive wet summers. We have only to keep down weeds, to keep the soil open and well broken up, to keep it well stored with fertility, and we may go on cropping year after year without giving heed to four-course shift or other local methods of crop rotation. But there must be no fitful haphazard work; our aim must be steady, our purpose sure. We *must* keep the soil clean as a garden; we *must* relieve "wet" land by drainage; we *must* apply manure to it every year. Instead of bringing the soil to the verge of exhaustion by over-cropping we should so sustain its high condition that each crop may be as full and abundant as is possible. Mark the term; dwell upon it, reader. Ask yourself if you really know how much increase the land may be made to yield. Is it the language of enthusiasm which tells us of eight or ten quarters of Wheat per acre? of twelve quarters of Oats being gathered off the same area of land? of twenty or thirty tons of Potatoes? of fifty to seventy tons of Mangold? A few days ago we called on a tenant who holds a small farm of only ninety acres, and we found him busily engaged in preparation for sowing Mangolds. The furrows were ready, and farmyard manure was being carted and spread in them, but the farmer could only afford one-fourth the quantity which we know to be necessary with an addition of 6 cwt. per acre of chemical manures. He, however, had no such manures, nor had he means to procure any. The result will be strictly proportionate—a meagre crop of small roots of little value for any purpose. How are we to decide between such a tenant and his landlord? Such a man feels the pinch of hard times severely. He comes to us for relief by a reduction of rent. In point of fact, he had a reduction some eighteen months ago, and he asked for another last Michaelmas. If he had the land almost rent free he would do very little good with it. Clearly such a man ought never to have had the farm. To turn him out now seems hard, but is it fair upon the landlord that he should have to suffer for the incompetence of an ignorant tenant? Suffer loss he must whatever is done, for if the tenant leaves and the farm is taken in hand, it is so exhausted that it will be a work of years to reclaim it and bring it into really high condition. Yet if the tenant remains he can do no good, and he will be always on the verge of bankruptcy.

It was advisedly that the soil was mentioned as a medium for conveying food to plants, for it ought never to be forgotten how largely plant-growth depends upon air, rain, and solar heat. Puny indeed are our best efforts in comparison to the gigantic operations of Nature, and every farmer ought

to know enough of what occurs in the economy of Nature to regulate his own work thereby. Then will the full value of green crops as a means of imparting fertility to the land be understood, and the culture of such crops will become general. This is a point of immense importance for the future, for the sowing and ploughing-in of such catch crops as White Mustard should form part of the process of reclaiming land that is both foul and poor. Clean the land in autumn if possible, but at the latest as early in spring as the weather admits of. Sow it with White Mustard 20 lbs. of seed per acre, give the Mustard a dressing of a hundred-weight per acre of nitrate of soda, plough in the crop when the seed pods are visible, and you will impart a rich store of fertility to the soil.

(To be continued.)

#### WORK ON THE HOME FARM.

With the dry weather corn-hoeing has been well done, and we now hope to see much less Charlock this summer. In some fields weeds were so scarce that some of the men were set forking out couch grass upon foul land; the use of forks and hand-picking for this work has to be resorted to wherever the grass has spread into thick beds, in order to eradicate it; the horse hoe, or whatever similar implement is most in local favour, being afterwards passed up and down and across the field, followed by harrows as many times as is found to be necessary. Sometimes a Cambridge roller is useful to crush the soil and to enable the harrows to pull out the twitch. Let all possible pains be taken with such work now, and as soon as the soil is as clean as we can render it by such means, sow it with whatever crop is considered most desirable. If it is very poor we cannot do better than sow Mustard for folding or ploughing in; if for permanent pasture we must take especial care to have the soil so well stirred and broken up as to make a fine deep seed bed. Folding of the breeding flock upon Rye is almost finished; the ploughs followed the folding as closely as possible, and harrows were used at once after the ploughs to break up the soil before it became hardened by exposure, our object being to sow Swedes there as soon as we can.

Stone and wood picking followed by the bush barrows and rollers has left the grass land in good order for the hay crop. Our most forward meadow is a large one upon the whole, of which old sheep were fattened in folds last autumn. The strong rich growth of herbage now affords pleasing evidence of the beneficial effects of the sheep-folding. The principal Grass in this meadow is Cocksfoot, and it certainly affords a greater bulk of hay and a more abundant aftermath than any other meadow we have. Sharp frost at the beginning of the month cut off some of the early growth of Clover, and gave a severe check to spring corn, especially Barley. We have a large field of Pacey's Perennial Rye Grass at an off farm, for which manure could not be spared, about which we found the bailiff somewhat puzzled. An inspection showed that the land requires draining, and we have decided to have the grass eaten off, to put in drains, to pare and burn the surface in July or August, then to break up the soil and sow Winter Oats in September with our usual half-dressing of home-mixed manures. Another half-dressing will be given early in the following spring, and we shall then confidently expect a profitable crop upon what is now the poorest field of the farm. Many farm buildings are now being put in repair, but none of the work is of an expensive nature. It consists rather of such things as broken tiles, plaster, fences, doors, and windows; walls with a few bricks loosened, broken gates, feeding cribs, and such things. Paint and tar will be used for all bare woodwork, both to protect the property and to give it a neat and finished appearance.

### FRESH AND FADING FLOWERS.

**N**OTHING is so tantalising to the decorator as to see the flowers he or his assistants set up, withering in a day or a few hours. Some of the flowers may be as fresh as ever, but those that droop so spoil the effect that patching becomes necessary, which, however much it may improve appearances, is not satisfactory. That some plants produce foliage and flowers of a more enduring character than others is well known. I do not

refer to this now so much as to flowers, whatever may be their persistence and enduring nature, fresh until the time of their natural decay. Some flowers are so generally employed that it is a matter of the greatest importance to so grow and treat them as to implant enduring qualities. This subject is well worth the attention of those who have to provide flowers for cutting and decoration in quantity and successionally in private establishments, whilst to growers for sale it is absolutely essential. The flowers that reach the decorator in the metropolis and large towns are some time in transit to the markets after they are cut by the grower, they have to remain until made up, then often have to be sent long distances, and yet they arrive as fresh as, if not fresher than, many that are furnished by home establishments. It is evident that one knows the best treatment to insure lasting qualities, and the other does not grow and treat the flowers in the manner best calculated to promote enduring properties.

The growers of flowers under glass for cutting must realise to the full the absolute necessity of the plants being grown in the greatest possible light in every stage, more particularly from the time of the flowers being visible to their expansion. The plants are then sturdier, their growth fully solidified, the foliage and flowers are stouter in texture, and the colours more highly intensified. They are not soft in texture and flabby as plants and flowers are that are grown at a distance from the glass and probably accompanied by shade. The endurance of flowers in a cut state depends much upon the way in which they have been produced. I know the difficulties of gardeners in many private establishments in having to supply foliage and flowers for continuous decoration with means altogether inadequate to a supply with the desirable enduring powers of those produced and supplied by the trade. I can cordially sympathise with such in their difficulties, and so will those who are chagrined at their flowers not lasting so long as other people's, when they come to understand the difference that exists in the growing of flowers that last and those that do not keep fresh beyond a few hours. There is nothing like trial for solving doubts, and prejudice is banished by experience.

Foliage and flowers for cutting cannot be grown in too much light, and this in all the stages of their development, the plants standing in positions where every ray from dawn to dusk reaches them. A sturdy, robust, character of plant must be obtained ere the persistent spray of leaves and bloom

is gained. It is the way to secure plants that will bear the dry atmosphere and cold draughts of rooms. The endurance of sprays of foliage and bloom, and of flowering or other plants, depends on their being well managed in the growing stage. It is the alpha and omega of the decorative value of plants. High culture, thorough assimilation of food supplies by exposure to the fullest amount of light and air consistent with steady progressive growth, is the way to secure floriferousness, size, substance, and bright colour of blooms. There are, of course, exceptions, as some grown in a high temperature and in the dark, like Lily of the Valley and Lilac—conditions diametrically opposed to those usually found indispensable to persistence—remaining fresh and crisp when cut or on the plant when exposed to a drier and cooler atmosphere. Such, however, are exceptional, and by far the greater number of plants grown under glass have endurance in flower in proportion to the way in which they have been managed through the time the flowers have been developing. Flowers of a smooth or waxy nature, such as Camellias and Hyacinths are much more lasting than those of thin soft texture.

Fern fronds and other foliage employed for mixing with flowers must be grown "hard"—i.e., in plenty of light and air, or their persistence is doubtful. Everybody likes to see Ferns with deep green foliage, also Palms for decoration, and there is no objection to it provided it can be had without taking from the endurance when cut; but this can hardly be effected without feeding with soot or other manure rich in ammonia, and even then the foliage is much paler than under similar condition of culture in shade, and such are of much less value for decorative purposes than those that have been specially prepared by exposure to the greatest volume of light in all the stages of their growth. The persistence of foliage employed for mixing with flowers is in exact proportion to the measure of good management in the growing stage. How frequently is the appearance of otherwise unexceptional vases of flowers spoiled by shrivelled Maidenhair? It is the result of taking it from plants in close, moist, shaded houses. It looks beautifully green under the conditions it was produced in, but is poor when exposed to the dry atmosphere of the dwelling house. The paler-coloured harder-textured leafage only is suitable for mixing with flowers, and to my thinking accords better with the bright colours than very deep green does.

Though growing flowers for endurance is of great importance, yet it is not everything. The flowers beyond being well managed in the growing stages must be properly treated afterwards if they are expected to last. All persons experienced with cut flowers know that those stood in water for a few hours after being cut and before they are made up, will last longer in bouquets, buttonholes, or in any other way that necessitates mounting. Some cut flowers and lay them in baskets or trays, keeping them out of water for hours before they are put in vases, or it may be packed for sending away, and then feel hurt when a complaint is made that the flowers want arranging afresh, or that they have travelled badly. The point is to cut them fresh and keep them fresh. Once let the flowers get limp, and then it takes a long time to restore their crispness, if, indeed, they are not parting with more moisture through the dry atmosphere than is being supplied to them by the withered stems and dried up channels. Cut in the morning and if the flowers are not wanted until evening or at once, be the purpose what it may, place them in water without loss of time, and keep them there until wanted. Those having next to no flower stem, as Allamanda, Stephanotis, &c., should be immersed in water altogether, and the more water they absorb the better they resist a dry and warm atmosphere. It is called "setting" by the bouquetists, and well it answers its purpose. Adiantums and all Ferns should be put in broad shallow dishes with an inch or so of water, so as to admit of the stems being immersed and the fronds or pinnules lying on or in the

water, cold water being the best, and the best position a cool and not very light room. So treated the endurance of the flowers would surprise many people, and make vases enjoyable that are often rendered disappointing by drooping and falling petals.

To retain the petals of flowers all decorative florists practise gumming, not of the flowers that are cut alone, but those retained for beauty on the plants. A slight touch of clear gum in the centre of a *Pelargonium* flower, for instance, seals the petals, and it requires very violent shaking to remove them, while if the work is expertly done the gum is quite invisible. The crowded masses of flowers on market plants is largely due to this process of gumming—that is to say, by that means the early flowers are retained until the later buds expand.—G. ABBEY.

### NOTES ON VINES AND WATERING FRUIT BORDERS.

A FEW days ago I was met by an amateur—a gentleman in a town not fifty miles from where I write, with the request “Come and see my Grapes,” and thither I went. Late last autumn his Vines had been carefully lifted, the drainage had been rectified and covered with turves grassy side down, and the Vines replanted in new soil, consisting of good turfy loam, to which one-fifth of horse droppings, old lime rubble, and wood ashes respectively had been added, and the whole well mixed. The roots were spread out all over the border, with a slight inclination downwards from the base of each Vine, and any that had become damaged in the process was cut clean off at the point of injury with a sharp knife. Incisions were made along the bare portions of the principal roots, and a few inches up the stems of the individual Vines to cause the emission of young roots, and then covered to the thickness of 6 inches with prepared compost, a surface dressing of short dung of half the thickness indicated being laid on the border. After this the whole received sufficient tepid water to settle the soil about the roots, which, like those of the Peach and Apricot trees in the orchard house close by, are confined to inside borders. Vines thus treated and allowed their own time to push into growth this spring could not very well do otherwise than break satisfactorily. They were carrying from fifteen to eighteen medium-sized bunches each, which were being thinned at the time of my visit, and which numbers, together with several of the lateral shoots, which were much too close to each other (9 inches in some cases), were recommended to be reduced forthwith to from 9 to 12 bunches according to the strength of each Vine and the size of the bunches, and the shoots to from 15 to 18 inches apart.

My friend's hobby being “fruit-growing under glass,” he has this year taken the management of the trees, &c., into his own hands, and being of a scientific turn of mind conceived the idea that by persistently stopping the non-fruit-bearing shoots or laterals and allowing those carrying bunches to make free growth beyond the latter, the flow of sap would thereby be directed into the fruit-bearing shoots, and that better results than could otherwise be obtained would be secured. I told him that the shoots and leaves would become overcrowded in a very short time, and so prevent the proper development of the latter as well as the ripening of the wood; and that by following a judicious course of pinching the laterals and sub-laterals larger and thicker leaves, having buds at their bases as large and firm as Filberts at pruning time, would be produced. My amateur and scientific friend's rejoinder was to the effect “that the leaves being the lungs of the Vines, he therefore concluded that the more leaves they had, irrespective of size or texture, the better it would be for the Vines and the crop.” However, acting upon my advice he has decided to treat a couple of the Vines in accordance with his own ideas, and to subject the remainder to the process of pinching the laterals and sub-laterals, and to compare the results.

Leaving the vinery and entering the adjoining orchard house the condition of the trees and the prospect of securing therefrom a crop of fruit this season were anything but encouraging, the trees suffering most severely through inadequate supplies of water. What little growth they made last year had been trained in the usual way to the back wall, and that of the central standard trees to a trellis fixed to the roof within 24 inches of the glass, which consists of 24-inch squares, secured to the purlines by small clips of copper and tacks, two clips and four tacks being used to each square. This done the borders containing the roots had a good mulching of short dung and an “application” of water, since which time (Christmas) no water had been given at the roots. This circumstance led to an inquiry being made as to the supply of water at

command, as well as the quantity given at the roots at each watering. The supply was good—namely, a tank, 4½ feet square, underneath the floor in one of the houses, and supplied by rain water conducted thither by gutter and stack pipes from the roofs of the glass and other houses; and it was remarked that this tank had never been empty since it was first filled, an admission which showed conclusively how inadequate were the supplies of water given at the roots, not only of the trees in the orchard house, but also of the Vines during their growing season, inasmuch as the tank when full of water would contain only sufficient for giving one house one fairly good watering. From this date (the middle of May) until the fruit has approached maturity such applications should be repeated two or three times a month according to the weather, and that the Vines, as well as the Peach trees, &c., would be considerably benefited and the results improved if a good surface dressing of Thomson's manure was laid on the borders prior to every fourth watering. This advice my friend has promised to follow, together with that of making a free use of the syringe on the trees morning and afternoon before and after they have set their fruits, and until the latter (Peaches, Apricots, and Plums) begin ripening, when syringing the trees and the house should be discontinued, and abundance of air admitted on all favourable occasions, leaving the ventilators open a few inches at night.

The importance of the facts and of the manner in which the cultural details indicated above are attended to must be my excuse for committing them to paper, in the hope that they may prove useful to readers of the *Journal*, as the case cited is but one of many, and by bringing the facts stated above under the notice of the responsible parties disastrous results may be avoided. I may remark that here from the middle of May till the middle of September we water our borders every ten days or thereabouts, but after the last-named date they require less frequent supplies at the roots. The borders prior to the house or houses being kept close receive a surface-dressing of horse droppings to the thickness of 3 inches, which once during the season (say May or June) is renewed. Our chief range of vineries is 128 feet long and 17 feet wide. This inside border, which, like the outside one, is well drained, receives about 5000 gallons of water at each watering—3000 gallons of clear water pumped and delivered from a large reservoir underneath the conservatory floor by one of Owen and Co.'s double-barrel force pumps, having 2¼-inch delivery hose attached, and 2000 gallons of liquid manure following immediately after from the manure tank in connection with the dung pound, where a goodly supply of stable dung (including a large percentage of horse droppings), in several stages of decomposition, is always at hand, and which is watered over with the pump and delivery hose indicated every time the supply is exhausted. This washes the substance of the heated dung into the tank, whence at a temperature of from 80° to 95° it is conveyed in water-barrows direct to the Vine and Peach borders in quantities as stated above. There need be no apprehension of the roots of Vines and Peaches sustaining any injury through copious supplies of undiluted liquid manure, had from such a source as that just described, being given to the borders in which they are growing.—H. W. WARD, *Longford Castle*.

### GLOXINIAS PLANTED OUT IN FRAMES.

IN 1878, during the Paris Exhibition, attention was drawn to the splendid collection of Gloxinias grown by M. Léon Duval of Versailles, and who annually grew 20,000 plants, Gloxinias being M. Duval's speciality. The plants have become very popular, and deservedly so; few are more showy, more floriferous, or easier of cultivation, thus being adapted to the requirements of nearly all classes of horticulturists; for it is not absolutely necessary to have a greenhouse to accommodate them, as I shall presently show. Who can fail to admire their wealth and richness of colouring, the bold appearance of their flowers, and their rich velvety green foliage? We have them in nearly all shades, from the pure white of *Mont Blanc* to the deep purple of *Prince Arthur*, the glowing crimson of *Vesuvius* and the rosy pink of *Rose d'Amour*. We have them self-coloured, bicoloured, and maculated, erect-flowered, semi-erect, and drooping, and to the impartial admirer they are all equally beautiful.

Natives of tropical America, they require a certain amount of artificial heat for their successful culture, but it is not essential that the temperature should be excessive, a moist, genial, regular warmth being most adapted to their requirements. Although their roots are fine and hair-like, yet they are rather gross feeders; indeed, owing to the delicate appearance of their roots they are apt to be very imperfectly nourished by those not versed in their requirements. The Gloxinia also, I think, derives a considerable amount of sustenance through its large porous leaves, and that may account in no small degree for the astonishing

results to be obtained when growing under the conditions indicated at the head of these notes. It also requires a constantly moist medium for its roots. It is true they need not be allowed to get very dry when they are grown in pots, but the fluctuations in the degree of moisture are often very great unless they are in very careful hands. And as it is rather a gross feeder, therefore when it is planted out in a suitable medium it can, as it were, attend to its own requirements, and is not so much at the mercy of the cultivator. It must not be supposed that I am advocating frame culture in preference to pot culture. For all ordinary decorative purposes the Gloxinia must be cultivated in pots, and I have had a full measure of success in that way; but when a quantity is required for cutting purposes I strongly advocate the planting-out system. Having devoted an ordinary two-light to that purpose every year since 1878, I do not write without experience in the matter.

Last year my frame was a failure, but that was not owing to the system, it was owing to very old and exhausted corms having been planted. Some were seven and eight years old, and I wished to try them in the frame for the sake of experience, as I was sure they would do no good in pots. Seedlings raised the previous autumn give excellent returns, but if they are twelve months old when planted, instead of three or four months, then the size, substance, and quantity of the flowers as compared with those the same age and same varieties in pots is something extraordinary. The most general method now adopted for raising a stock of Gloxinias is from seed, but if it is desired to keep certain varieties already in stock, then they should be propagated from leaves, or by division of the corm when starting into growth. When the latter plan is adopted the cut surface should be dressed with lime to dry up the sap. I have sharp sand placed around them when being potted. If seed is sown in pots, pans, or boxes containing a couple of inches of fine peat with a liberal addition of sand, and placed in an early Cucumber frame at the end of January or beginning of February, and kept growing freely by pricking off and potting until they are established in 4 or 4½ inch pots, they will commence flowering about June, some will be later. The seed should be sown thinly and evenly, and barely covered with the soil. A piece of glass placed across them will prevent too rapid evaporation. If a piece of glass is not handy a newspaper will be as well or better. This may be kept over them until the seed germinates, when the seedlings should be gradually inured to the light, and only be shaded from strong sunshine; and if grown as recommended the strongest of them will now be ready for planting out.

As the present time is favourable in every respect, numbers of frames being emptied of their contents and perhaps nothing else in particular to place in them, let those who require Gloxinias for cutting purposes try a frame, and I think they will not need to be reminded to do it again next year. A half-spent hotbed will be better than a new one, as there is a danger of the latter being too hot and steamy. Let an old bed be turned over, and if there be a gentle warmth it will be sufficient; allow it to settle for three or four days, then tread it down level, place on the frame, and having mixed a compost of two parts peat, one of leaf mould, and one of sand, place it in the frame to a depth of 4 inches, and plant the Gloxinias about 18 inches apart; water with a rose without wetting the foliage, leave a little ventilation, and shade from the sun's rays. In due season the flowers will appear, and will continue to be produced until the approach of winter. As the plants grow and come into flower great care must be exercised in watering. Be sure that they require water before applying it, and when it is being done pour it under the leaves and not in the centre of the plants, being very careful to avoid wetting the flowers.

So effective are Gloxinias grown in this way it is a marvel that some of our enterprising nurserymen or enthusiastic amateurs have not gone to the length of planting a house full of them. Carefully arranged at planting time, and the sides of the beds and stages draped Torenias, Thunbergias, Panicum, and Tradescantia, they would vie with the Orchid exhibitions and Amaryllis exhibitions; but as I think they are more essentially an amateur's rather than a nurseryman's flower, I shall hope to hear or read, ere the summer is over, of some lady or gentleman having the courage and enterprise to carry the above suggestion into effect, and thus have an exhibition of their own both beautiful and uncommon, and one also costing very little money.

In conclusion, I ought to say—and this is important—that the soil in which Gloxinias are planted or potted should not be pressed firm, but be kept loose and open as possible. For the guidance of those who would prefer to have a few select sorts instead of running the risk of having a batch of inferior varieties amongst seedlings, I append a list of few which I have found to

be of sterling merit and rarely surpassed for the quality of their flowers and richness of their colours:—Belford, Boule de Nieve, Charme de Lutece, Charles Dickens, Clytis, Gamos, Miss H. de Rothschild, Marquis of Lorne, Mr. Gladstone, Madame Patey, Madame Duval, Mont Blanc, Ne Plus Ultra, Princess of Teck, Prince Arthur, Rose d'Amour, Roxelane, Sir S. Northcote, Sang Goulois, Vesuvius, William Goldring, Prince Leopold, Madame Thibaut, and Rubens.—J. UDALE, *Elford, Tamworth.*

#### CHOU DE GILBERT AND CHOU DE BURGHLEY.

MR. ABBEY on page 292 described Chou de Gilbert as a Cabbage-Brussels Sprout, whilst "Thinker" considers it—I speak from memory, for I have unfortunately mislaid the Journal of May 6th—a Broccoli-Brussels Sprout. Mr. Gilbert kindly sent me some plants last summer, and up to about six weeks ago I found it as Mr. Abbey describes it, and since then it has developed into a Broccoli-Brussels Sprout, or as I should feel inclined to call it, a Chou de Burghley Brussels Sprout. The sprouts, unlike the Brussels, are elongated, tapering in some cases to a sharp point, and the stems are well clothed from top to bottom with them. They are very delicious, being very marrow-like in flavour. Mr. Gilbert, I understand, has several types of this vegetable, and doubtless we shall hear of some more "Chous."

Chou de Burghley is very much improved. I have been cutting it in all stages of growth since November, and I have now about half a dozen, which are forming nice Broccoli heads inside their Cabbage envelopes. One I have retained for seed, for it is quite unique. It first developed several sprouts up the stem, which soon became miniature Broccoli, the flower not being hidden. These I cut and ate, keeping my eye on the head for about ten days, and to-day, May 12th, I removed gently the outer covering, and found within a perfectly formed white Broccoli. This is the right kind of sprouting Broccoli, if it can be perpetuated.—H. S. EASTY.

#### THE BOILER CONTEST AT LIVERPOOL.

THE following are the conditions of the boiler contest at the Royal Horticultural Society's Great Provincial Show to be held at Liverpool from Tuesday, June 29th, to Monday, July 5th, 1886 (inclusive):—

1, Competitions will be in three classes—viz:—

Class 1,	.. .. .	2000 feet.
" 2,	.. .. .	1000 "
" 3,	.. .. .	500 "

2, Each competitor to supply and fix his own piping and boiler, with all necessary fittings complete, at his own expense.

3, The Royal Horticultural Society will supply the fuel and the thermometers required for the contest.

4, All the hot water piping to be 4-inch (inside size). The chimneys not to exceed 20 feet in height, above the ground level.

5, The height of flow-pipe above top of boiler not to exceed 24 inches (overall) at boiler, nor to rise more than 6 inches in 100 feet.

6, Each boiler to have not more than 1 flow and 2 return connections.

7, The piping to be fixed as under:—

In the 500 feet, 3 flows and 3 returns; two deep.

" 1000 "	5	" 5	" "
" 2000 "	10	" 10	" "

with 3, 5, or 10 syphons or boxes respectively, at extreme end.

8, The total amount of piping in each case not to be less than specified.

9, The competition in each class will begin simultaneously, about mid-day, and last for 24 hours.

That for the 2000 feet on the first day of Show.

" 1000 "	" "	second day of Show.
" 500 "	" "	third day of Show.

10, In the case of boilers set in brick-work, they must be fixed and the brick-work dried by firing, and thoroughly cooled down again by the time of competition beginning.

11, Each competitor must be prepared to fix the thermometer on the part of the plain piping where directed, on the morning of the competition.

12, Every point for and against each boiler can be pointed out, and will be carefully considered by the Judges, and may be embodied in the report of the contest, so that competitors should carefully avoid anything that might tell against them.

13, Intending competitors must send in, at time of entry, full particulars as to heating power, &c., of their boilers, with price at which they are prepared to supply the public, which will be published.

14, One or more medals will be given in each class, if the Judges consider the competition worthy of such an acknowledgment.

Applications for space should be made on or before Saturday, June 12th, to Mr. A. F. Barron, Superintendent, Royal Horticultural Society's Gardens, Chiswick.

#### NOTES FROM MY GARDEN IN 1885.—No. 3.

##### GREENHOUSE.

I OFTEN quake when I am writing these notes lest someone who may not know the small extent of my garden, and, reading them, might be tempted to pay me a visit, and I should seem to him a deceiver, and be met by the exclamation, "For what in the world did he make all this fuss about his garden? I don't see anything very particular about it." Well,

so it may be; but having the assurance of so many that these brief notes are helpful to them I still venture to continue them. Small as it is, I do comfort myself with the notion that there is at all times something to see, and that when anyone does happen to come who knows what things are they do not go away quite disappointed, and very often carry away with them something they have not got, and thus even my little greenhouse, small though it is, becomes a source of content, and surprise is often expressed that I can do so much with so small a house. I think that one of the achievements I most pride myself upon is that of being able to grow things requiring such different treatment in the same house. One is often told, for instance, that it would be utterly useless to attempt growing hardwooded plants and Geraniums and other softwooded plants in the same house. Well, I have done so. I have at this moment some small plants of Azaleas covered with bloom and in full flower, while I have also decorative Pelargoniums, such as *Volonté Nationale alba*, *Madame Lemoine*, *Madame Thibaut*, &c., in flower. Instead of repeating a thrice-told tale I shall content myself with enumerating a few of those things with which I succeeded well, recording at the same time my failures.

Some time ago I was anxious to see whether I could grow a few of the cool house Orchids, and through the kindness of friends tried a few plants of *Masdevallias* and *Odontoglossum Alexandræ*. For the first two years, as our winters were very mild, they did well and flowered nicely. I felt that last winter would be a test, and so it has proved. The *Alexandras* succumbed, but the *Masdevallias* have stood it well, look healthy, and are now showing flower. I must therefore conclude that they will stand a low degree of temperature, and when placed in a shady part of the house where they can get moisture will do well, but that I must abandon the hope of growing *Alexandræ*. My only other Orchid, *Disa grandiflora*, has done admirably. I have now a pan of it which I can safely say is as fine and healthy as I have anywhere seen. It is in one of Mr. Dominy's Orchid pans, which has holes round the sides. Not only is there a presence of five or six spikes of bloom, but shoots are protruding from most of these holes. I have been able to give to several friends pieces of these plants, but I find it difficult to impress upon them the fact that *Disa* does not require heat, that it wants only peat and charcoal in lumps to be potted in, and that it does not care how much it is syringed. It is now just at the door of the house, getting all the air possible and not much sun—in fact, only getting it directly in the afternoon. Another pan that I have of it is not so vigorous, but this I account for by the fact that it has broken itself off into a number of plants, and its vigour has been expended this way instead of in flowering. Another season they will be planted in smaller pans, where they will not have so much liberty for breaking off into small plants. I find that they do not object to being divided, and, in fact, they are as easily grown as any plant I have.

Equally well did my *Lapagerias* succeed last year. Someone told me—I think in the *Journal*—that I should not go on much longer with them, and rather poked fun at my putting them into a box instead of pots. Nothing could be better than the way in which they did last year, giving me a profusion of bloom and growing very vigorously. I took care to shade them more than I did the previous year, when the hot sun took the colour out of roses. Last season it was as well coloured as I could wish. Of course the plants are mere pigmies to those which are grown where there is abundance of room for both roots to run in and for the growth to ramble over. To me the great pleasure is that in a small house I can grow it successfully without disturbing the other plants.

I have little to say on the subject of hardwooded plants, of which I have only a few. My small plant of *Azalea imbricata* has flowered profusely, but I question if the flowers are so double as in former years. This is generally considered a miffy sort, and I find that it has been eliminated from some catalogues. It has done very well with me, and is remarkable for its doubleness. Indeed it would be difficult to imagine it to be an *Azalea* when a bloom is taken from it and mounted on a wire. *Empress of India* is very fine, but its colour is not so pleasing as some of the others. Among whites I see nothing to excel *Apollon* and *Madeleine*. I cannot say much about *Camellias*. My plants had grown too big for me, and I was obliged to get rid of them, exchanging them for smaller plants, and these have not done much in the way of flowering. I am rather inclined to think that I do not care quite so much for these very beautiful flowers as I used to do. Nothing can be more exquisite than the white varieties, but there is a preciseness about them which, combined with their lack of perfume, takes away something from them.

Amongst softwooded plants there have been some things which did very well, and are very great acquisitions; for instance, that capital decorative Pelargonium sent out by Mr. F. Perkins of Leamington, *Volonté Nationale alba*; in profusion of bloom, vigour of constitution, and purity of flower, it cannot possibly be excelled, and is without doubt the very best decorative plant of any sort that has been introduced for some years. For cutting it is invaluable, their flowers do not fall as the *Zonals* do, and hence are much more useful, while for the stage they are equally desirable. The plant is one mass of flower, and its whiteness contrasts well with the brighter coloured varieties. *Queen of the Belgians*, sent out by Mr. Cannell, is by far the best of the white *Zonals*, its flowers are well formed, substance is good, and the truss large. I do not think it would be possible to beat this in its class, what it might do out of doors I cannot say. Most of the white *Zonals* have a tendency to acquire a pinkish tint when exposed to weather, and whether this would do so I cannot say. Another most satisfactory Pelargonium has been *Madame Thibaut*, double Ivy-leaf. There is nothing in the way of hybridising that has been more wonderful in its results than the improvement of the old Ivy-leaf Geranium. When one recollects what a poor little insignificant

flower it was, and also the first attempts made to improve it, it is certainly amazing to see such a flower as this—a large handsome truss of flowers, as double as those of the ordinary double *Zonal*, and of a beautiful bright clear rose colour. Moreover, the plant is thoroughly an Ivy-leaf, and has the graceful habit they all possess, and gives its trusses of bloom very freely. Of Show Pelargoniums I have not much to say; they seem to have reached almost their limit; and taking those of the last three years, I do not think there is much advantage, while it almost seems as if the improvement in other sections, the *Zonal* Ivy-leaf, double and decorative, were driving them out of the field.

Bulbs have a large share in my arrangements, and I rely very much on them from time to time, beginning with Hyacinths and Tulips in spring on to Lilies in the autumn. I used at one time to grow some of this latter beautiful tribe for autumn decoration, but have somewhat diminished my culture of them in the house and increased it in the open border. I have hitherto done exceedingly well with Cyclamens, especially those of the Giant strain, but this year they were a comparative failure. I could not understand why, as I had, as far as I knew, in no way deviated from my former practice; but on examining them I found there must be something wrong, as there had been but little root-action. On inquiry I found that an alteration had been made in the compost used, and I have no doubt this was the cause. Amongst the prettiest of these is Sutton's Butterfly, a pure white. I have before now highly commended *Freesias*, but have been told I should find it difficult to get them to flower a second time. I have, however, I am happy to say, not found it so. I have had them blooming freely this year; in fact, more freely than a few imported bulbs that I tried. My pots of bulbs were basked in the sun before being put by, and I am inclined to think that this had something to do with it. I had also raised a number of seedlings, many of which flowered, but I saw nothing remarkable amongst them. No one sees them that is not delighted with their appearance and perfume, and if there be no more difficulty with them than I have experienced they ought to be grown in every greenhouse. I wish I could say the same of *Ixias*; they never do anything with me the second year, and even in the first year some of them are not satisfactory. Nothing could have been more vigorous and healthy-looking than they were until the flower stems were just on the point of opening, and then the foliage began to wither, and although the flowers expanded, yet the plants looked sickly. Why this is I am at a loss to imagine, especially as the kindred genera of *Sparaxis* and *Babiana* do very well with me. *Ornithogalum arabicum*, an old and almost forgotten bulb, is very useful and ornamental, and the flowers, pure white with their black bars in the centre, are very attractive, but why the shoots have not as yet made their appearance above ground I cannot understand; they seem sound, but they won't move. Another bulb that has puzzled me is *Milla biflora*; it does not seem in the least inclined to move, and yet one hears glowing accounts of it from those who have grown and flowered it. Can anyone tell the secret of growing it? Another old-fashioned bulb I tried last year for the first time, *Eucomis punctata*; it gave me great satisfaction, and is very enduring, the spike of flowers lasting some weeks. Tuberous *Begonias* were also a success, but everybody can grow them. I must own to a liking for the strain sent out by Messrs. Sutton called the Reading Beauty strain; the flowers are not so large, there is a good infusion of *Pearcei* blood in it I fancy, but they are very free flowering, and the flowers come away well from the heart of the plant differing in habit from the ordinary large-flowered varieties, which have now reached such a size as to amount in my mind to coarseness.

I know nothing that tends more to make my small house fresh and gay in the spring months than a few pots of a very common annual, *Schizanthus*. The seed is sown in July or August, and the plants pricked off into 32's, four in a pot, and their graceful slender growths and profusion of light and prettily marked flowers make them very desirable subjects. I have in larger places seen them suspended in baskets, and the flowers drooping over the sides and hanging down some 2 or 3 feet, but these are things I cannot attempt; "small boats must keep near shore," and yet, perhaps, some will say I attempt a great deal too much; perhaps so, but it pleases me. Besides these things that I have mentioned as specially deserving notice there are a number of odds and ends which from time to time make their appearance—*Primulas*, *Cinerarias*, *Aquilegias*, and so forth, but I have noticed those which I thought deserving of being mentioned for the encouragement of those who have small greenhouses, and in them, as in a small garden, selections, not collections, must be the rule. I might fill my house with a collection of one plant or another, and while they were in bloom they would look gay enough, but what when they were over? Whereas now from early spring to late autumn I have always something to gratify me, and few greenhouses, I fancy, give their owners more pleasure.—D., Deal.

#### SALADING.

A DAILY supply of salading for the table is a speciality here, and always gets the highest encomiums pronounced on it; but, from statements of many visitors entertained here, it is not so everywhere, and no doubt the gentlemen that brought about the salad contest were quite aware of the paucity in the daily supply of home-grown salad fresh gathered a short time before using. But to confine it entirely to Lettuce, as some are constantly trying to teach us, is entirely wrong. Salad plants are grown to be used in many ways, without the usual dressings and mixing in the salad bowl. Sutton's Crimson Flake is a good addition for the salad bowl in the way of Chicory. Silesian, Brunswick, and Long Magdeburg Chicories are very wholesome and palatable eaten as Celery when well grown and blanched in a cool place. Rampions forms a very good adjunct

to the breakfast Radish, but are not often met with. A few sprigs of Tarragon give a warmth and flavour to the salad bowl far before Tarragon vinegar. When I lived with the late Mr. John Cotes of Woodcote he could at once detect the absence of Tarragon in his daily salad. I would advise my younger friends of the profession to keep salad-growing to the front and supply the table well, and see if it is not appreciated equally as well as growing a good Orchid. A nice plate of fresh Cress, Radishes, Rampion, Lettuce, and the despised young Onion are liked by the family here. Let others say what they will, the Englishman will not be easily talked out of his salad, of green Onions and Lettuce; let the Frenchman prefer the Lettuce alone.—GEO. BOLAS, *Hopton Hall Gardens*.

### CATTLEYA BOWRINGIANA.

UNDER the appropriate name of *Cattleya autumnalis* this Orchid was first shown by Messrs. J. Veitch & Sons at one of the Royal Horticultural

fig. 71.—*Cattleya Bowringiana*.

Society's meetings in October last year, when a first-class certificate was awarded for it. The name then bestowed upon it was, however, only provisional, and now it has received the designation given above in honour of J. C. Bowring, Esq., Forest Farm, Windsor, a well-known amateur, who has been successful in several hybridising experiments. This *Cattleya* is an introduction from Central America, and is related to *C. Skinneri*, but its chief merit is found in the season at which the flowers are produced—namely, late autumn, and the plant is especially welcome on this account, as the number of *Cattleyas* in flower and Orchids generally is very limited at that period. The flowers do not exceed 3 inches in diameter as seen at present, the petals and sepals narrow, of a purplish crimson hue, the lip much richer crimson with a white throat. It flowers freely, the spikes bearing in some cases as many as ten flowers, which last well. *C. Bowringiana* must be regarded as a valuable addition to the genus, and one that will probably become very popular. The illustrations (kindly lent by Messrs. Veitch & Sons) show the character of the species faithfully, fig. 71 representing a truss of flowers, and fig. 72 a single flower.

### MONK'S MANOR, LINCOLN.

MONK'S MANOR, Lincoln, the residence of R. Ruston, Esq., M.P., is charmingly situated on the hill near the fine old cathedral. From the grounds a good view is obtained of the city and the surrounding country

for miles. The gardens are attractively laid out, and the flower beds would have been very effective had not the severe weather made sad havoc among such plants as *Myosotis*, *Silenes*, and *Wallflowers*. Fruit trees are looking remarkably well and promising, the finely trained cordon and pyramid trees of Apples and Pears especially. The Peach trees in a long lean-to house are well set with fruit, and quantities of Strawberries are ripening there: the variety grown is *Vicomtesse Hericart de Thury*. The vineries, too, contain some vigorous canes. The back wall of one house is covered with *Citrus decumana* (Shaddock), bearing a quantity of large fruits. In the Black Hamburg house may be seen a fine specimen of *Dendrobium Bensoniæ*, grown in a basket close to the roof with pseudo-bulbs 2 feet in length, and will shortly be a mass of bloom. Mr. Coulling appears to have hit upon the right plan of growing this fine Dendrobe, which is rather difficult to manage in some collections of Orchids. It is allowed to make its growth with the Vines, resting at the same season as they, and no doubt on account of the growth being made quickly and having a long period of rest is the chief cause of such good results.

In the stove, among the usual occupants, such as *Caladiums*, *Crotons*, *Ferns*, and *Palms*, &c., are many choice Orchids. Another plant to attract attention is a specimen of *Anthurium Andreanum* bearing large spathes 9 inches deep and 8 inches across, with a greenish tinge round the upper margin. The back wall is clothed with a dense mass of *Ficus repens*. A large plant of *Poinsettia* is growing amongst it, 13 feet high, with a very thick stem; a few of its scarlet bracts are still to be seen enlivening the dark green wall surface. Among the Orchids growing and flowering well are *Dendrobium Deari*, with growth 2 feet long covered with healthy green foliage; *D. crepidatum*, *D. heterocarpum*, *D. Dayanum*, *D. Devonianum*, *D. crystallinum*, *D. luteolum*, *D. Paxtoni*, *D. thyrsoiflorum*, and *D. primulinum* with growth 3 feet in length; *Cattleya lobata*, *C. speciosissima*, *Anguloa Clowesii*, and *Sobralia macrantha* with thirty growths in a 9-inch pot. They all bear evidence of good culture, and afford

Fig. 72.—*Cattleya Bowringiana* (single flower).

another proof that Orchids may be grown satisfactorily without having houses specially built for them.

In the conservatory and greenhouse are many plants of interest. *Lapagerias* and double *Clematis* occupy the iron supports. A plant of *Sarracenia Cheloni* with many leaves has six of its quaint-looking blooms. Some of the best forms of double *Cinerarias* are grown, and a large plant of *Pelargonium Wonderful*, or Double *Vesuvius*, trained in balloon shape, is 4 feet through, bearing scores of trusses of scarlet flowers. Rollisson's *Unique* is represented by several good plants, and is very useful for cutting. Some good varieties of *Amaryllis* are in bloom, and many other plants, the condition of the whole, and the entire garden, reflecting great credit on Mr. Coulling, the able gardener in charge.—G. W. CUMMINS.

### GARDENERS AND PREMIUMS.

It may be useful to state and the fact should be recorded, that some of the most noted gardeners in England, and particularly in Scotland, who have sent out more head gardeners than almost any others, never required a premium from any of their men, although they might have been justified in doing so on the strength of their own reputation as gardeners alone. I do not, however, find fault with any gardener taking a reasonable premium from journeymen or apprentices, provided he is prepared to help them in their education, and push them on as far as he can. Premiums are demanded in many professions and trades under such conditions. I could furnish you with cases in which head gardeners and others have paid £100 to estate agents and surveyors for their sons for three years' instruction, the young man doing duty daily all the time and receiving no remuneration, but either employment at a corresponding wage, or assist-

ance to a situation when the three years expired. The objectionable cases in gardens are those in which the gardener trades upon the name of the place he superintends, and takes premiums from the men for the bare privilege of working in the garden in any department for perhaps two years, when they are compelled to leave and go elsewhere without any further assistance. This is what used to be done some years ago in a noted garden in the Midlands. I wrote to the chief myself not long after he took charge on behalf of a young man I was interested in, and either £5 or £10, I forget which, was asked as a premium, the man to leave at the end of two years. I agreed to pay the sum on the condition that the man would be promoted or assisted into a situation elsewhere, provided he gave satisfaction, but the gardener declined to bind himself in that way, as he could get pupils who would not insist on such terms. I need hardly say he did not get my man. In this same place the wages have always been lower than anywhere else in the neighbourhood, so that a premium became a hardship to many young men there, as they found out. Whether the present superintendent there requires premiums or not I do not know. I can give you names and particulars privately if required, and I may add that the head gardener who took the premiums bestowed no personal attention on his pupils, and had not been long there. If they made good use of their opportunities, well and good, either way they had to pay. There is nothing easier than for head gardeners to get premiums if they choose to lay themselves out for them; but, personally, I have never been enamoured of the system, although I have had many offers, and constantly receive them, for the reason that it is not worth while, pecuniarily, unless premiums are taken from all, and a regular system of limited periodical service carried out; but the worst feature of the system is that it ties the hands of the master, and thrusts responsibilities upon him, and often indifferent men, both of which he is much better without. I have heard of gardeners who have been much worried by premium men, who presumed in consequence, and should not wonder if some of the cases recorded in your pages lately were of this sort, although I know nothing of them. As to wearing gloves when stoking, these are provided for the purpose in all good places where much stoking is necessary, as it tries the hands severely in winter. Housemaids are regularly provided with gloves to brush the grates. Rings, over-much jewellery, and other signs of foppery, few real gardeners like to see, because the paltry vanity such things indicate is seldom associated with good sense and practical ability. I know many of the best gardeners personally, and none of them are fops or wearers of rings.—A GARDENER TO AN EARL.

YOUR correspondent "W. P. R." has very kindly acted upon the suggestion of "A Thinker" at page 353, and sent me copies of the Journal for April 29th and May 6th, in the first of which I am directly charged with treating a young man with positive hardship and injustice; and in the number for May 6th appears a statement of a case showing what might be my position in regard to the circumstances mentioned at page 342. The premium of £5 was to be paid down, and on being asked after his arrival here how he intended to pay the amount, he replied that he had a friend in London with whom he had been staying who would lend him the money. In about a fortnight after he informed me that he had written to this friend, but could get no reply from him; he, therefore, suggested to me that I should keep so much per week from his wages until the £5 was paid, and inasmuch as he was paid for eleven weeks I deducted from his wages a total sum of 22s., which is at the rate in round figures of £5 for the year. He never asked for an explanation. How could he, when it was his own suggestion? He was set to do other work after he had shown that he was unable to perform satisfactorily work that he was engaged to do (after much forbearance). The next sentence of "W. P. R." is also untrue. Nearly all my young men stay with me from two to five years. During a period of ten years I have only had two who have stayed but twelve months. I do not include the young man who is the cause of this discussion. I have never taken more than £5 from any man, no matter how long he has been with me; therefore, the intricate calculation and polite innuendo of "W. P. R." is uncalled for. The insinuation that my noble employer makes me an allowance in lieu of premiums is untrue and entirely devoid of foundation. Many of the young men that have come in these gardens have been experienced men, and have paid no premium. As "W. P. R." directs his attention and questions to "Observer" at page 376, I will leave "Observer" to deal with him; and as "W. P. R." for obvious reasons abstains from giving either his own name or mine, I will content myself by remaining—THE EARL'S GARDENER.

[The "Principal Foreman" in the garden in question also writes, stating that "the young man in question did ignore my authority in not keeping proper time."]

"W. P. R." at page 376, conveniently overlooks the fact that he and I occupy different positions in regard to the matter under discussion. He cites what he believes to be a hard case at page 342, and that, apparently, from purely *ex parte* statements, and proceeds to make certain serious specific charges against some particular individual; and he appears to think that because he has not mentioned names he is therefore acting in a very careful and discreet manner. Does it not occur to "W. P. R." that he would have been much more careful and discreet if he had made some attempt at investigation privately before rushing into print? Has he written a single letter to the gardener in question, inquiring how far the young man's statements were correct, and what his reasons were for discharging him? If "W. P. R." has not done that I think he has been both discourteous and unfair to the gardener in question.

My position differs from "W. P. R.'s" in this respect—I am, unhappily, acquainted to a certain degree with both sides of the case I quoted, and was, as my letter showed, the means of the engagement between the head gardener and young gardener; and as it is just possible that the matter may yet be carried to a court of law—especially if a certain party does that which "W. P. R." thinks I might have set an example in doing—I do not wish to precipitate such a result; but the gardener to whom I have alluded is quite willing that I should give his name. I will neither give his nor the young man's for the above reasons, but "W. P. R." can have my name and address by applying to the Editor of this paper. In withholding my name from the bottom of this letter I am not actuated by feelings of either modesty, fear, or shame.

My friend did not suppose the young man would wish to go to him after receiving such a letter, but as he is of a warmhearted and generous disposition, he had not the heart to tell the young man he would not have him after the former had written accepting the engagement, and decided to give him a trial; and, in doing that, he did what I would not have done after I had seen the letter in which he had referred to his father in such "filial" terms; and I did not hesitate to write back and say that "I would not have engaged such a man upon any terms." The young man in question had not "£5 in his pocket," nor could he borrow the sum from the "friend" with whom he had been staying, and who he said would lend it him; therefore "W. W. R.'s" observation on that point is quite beside the mark. I suppose the young man agreed to pay the premium in order to have the opportunity of learning that with which he was unfamiliar, as I and scores of others have done, and not for the particular purpose of being allowed to do the work he was specially engaged to do on his representations that he was accustomed and competent to carry out such work.

"W. P. R." acknowledges that "considerable forbearance" was exhibited towards this young man; but although, in his own view, no other but philanthropic motives are very clear, yet he is reluctant to credit my friend with such motives. In the absence of any other clear motives, "W. P. R." has no alternative but to so credit him. I cannot see anything peculiar in the fact of the £5 having to be paid during the first year; as a rule, it is during the first year that men give the most trouble, and sometimes it happens that after they have been allowed twelve months' credit they have left their situations and "forgotten" that they owe anything. My friend informs me that his predecessor experienced that. I have no personal experience in the matter, for the reason that I have never yet taken a premium off a young man; but my experience on the subject is that they who get the most information imparted to them gratis are by no means the most grateful for it, and I do not think I shall long continue my practice in that respect, although I have done so nearly eleven years.

I do not feel called upon to answer "W. P. R.'s" last inquiry, but for the sake of courtesy I will do so. The number of young men who have not stayed more than twelve months in the gardens alluded to during the ten years my friend has been there—and where there are six in the bothies—I understand are three, and that number includes the young man in question. During the first part of the period of ten years there were but four in the bothy, latterly there has been six, thus giving an average number of five. There has been a total of fifteen changes during the ten years, this gives an average of three years and four months per man. Can "W. P. R." cite another case under similar conditions where the same average number of young men stay the same or greater average length of time? I base my statements upon information supplied to me from the pay sheets, which I consider to be far more reliable than one-sided statements.

"Another Observer" admits my case is the same as he mentions on page 376, and says that he has sifted out a few facts in connection with the same, and says there is good reason for disquietude and inquiry, and appeals to the Editor for a fair hearing. I make no such appeal to him, because I am confident that, having admitted such a serious charge against a gardener into his paper, he will not close its columns until the matter is brought to a clear issue, and provided the question is discussed in a proper manner. I notice that, although he says he has sifted out a few facts in regard to this case, yet he does not attempt to refute or disprove any one of the positive statements that I made on pages 353 and 354, but contents himself by making calculations on a qualified statement—viz., "about 24s." I qualified the statement because I did not remember the exact sum, and by quibbling over a few days in regard to the words "several months." The young man was employed ten weeks and four days, and I am informed he was paid for eleven weeks; eleven weeks come nearer the period of three months than two months, and as any small number over the singular comes within the meaning of the word "several," I contend that my statement in regard to time was correct.

My friend positively states that "Another Observer's" assertion as to the amount deducted is absolutely incorrect. He says it was 22s. and not 27s., as stated by "Another Observer;" therefore his calculations are worthless, and his knowledge of that and similar cases *nil*. I made no defence of too much dress, consequently there is none for "Another Observer" to pass. When a case has to be propped up by incorrect assertions, quibblings, or garbled quotations it indicates weakness indeed.

"Another Observer" says, "The charge of not turning out and ignoring the foreman's authority is disputed," and calls for the foreman as a witness. Well, he shall have him, and here is his testimony as given last Saturday in reply to questions on the points "disputed" but not denied: "I had to speak to the young man in question as to turning out

at the proper time more than once, and after great forbearance had to speak to his chief, but apart from all that, he was no use at his work."

It is usual in "other places" for respectable "counsel" to throw up their briefs when they find their own witness give evidence for the "other side" and their "facts" to be founded on "fiction." What does "Another Observer" intend to do? My friend informs me that he has never taken more than £5 from any man, no matter how long he stayed, and as this case and "W. P. R.'s" appear to be identical, inasmuch as he has forwarded copies of *Journal* to my friend, as suggested by "A Thinker," it will be as well in future to confine the discussion to the subject in dispute—viz., Has the earl's gardener deducted more than he is legally entitled to from the young man's wages? was the agreement for the £5 to be paid "down," and failing to be able to pay the £5 down, did the young man himself suggest to the earl's gardener in the large conservatory that he should deduct an unspecified sum from his wages? The earl's gardener takes the affirmative to the above questions. I now content myself by saying the threat at the end of "Another Observer's" letter is characteristic of the private letters, and will have about as much effect.—OBSERVER.

### PROFITABLE GARDENING.

#### ROSES FOR MARKET.

YOUR correspondent, "J. M., Somerset," page 372 of the *Journal*, has made out what appears a good case at "first sight," in writing on the *Maréchal Niel* Rose (page 373); but let us examine it a little more closely. It looks very nice in print to see 2000 *Rose* blooms realising about £25; there are, however, other things to be taken into account. How much has the house cost in working during the year in fuel, &c.? There is also cutting, packing, and carriage of the flowers to market. Deduct the above items, and then how much is there left out of the £25, which alone can be looked upon as actual profit?

I can show a little of the other side of the question of *Rose*-growing and marketing surplus blooms. It has, perhaps, fallen to my lot to have as many *Roses* under glass to care for as most men in medium-sized private places. We have three houses devoted to the growth of *Roses*, more or less, and I have sent over 500 blooms per week away during some weeks in the spring, of course in different varieties. Several of them are Hybrid Perpetuals, of more use than *Maréchal Niel*; besides using a quantity at home and giving some away amongst friends. I have sent a few for your inspection, which may be taken as under the average quality, some of our best varieties being out of bloom just now. The highest price I have received this spring has been 2s. per dozen at Hull, and for the last month 1s. 6d., and now 1s. per dozen. The last week in April I received from Covent Garden at the rate of 10s. per 100; the first week in May 3s. per 100 blooms, and many of the blooms much better than those forwarded to you were.

I think the readers of the *Journal* will do well to think twice before they go very extensively into *Rose*-growing under glass for profit, especially as far north as Yorkshire. I am afraid such glowing accounts of *Maréchal Niel* *Rose* for profit will not be to the advantage of many gardeners who have to market surplus flowers. The question will be put by several employers to their gardeners, when perhaps their hands are already full enough of other work, Why don't you make it pay better?—W. W., *East Yorkshire*.

[The *Roses* received are very fresh and bright, with good foliage, and may be described as good buttonhole and bouquet flowers.]

WE understand that it is the intention of Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, to make a fine display of TREE PEONIES and other choice plants in conjunction with the show of pot *Roses*, Azaleas, &c., in the conservatory at South Kensington, on the 25th inst.

A NEW edition of Mr. Lewis Castle's "TREATISE ON ORCHIDS" will be published in a few days. It has been considerably enlarged, contains a chapter on cultivation, with other additions, will be bound in cloth and sold at the same price as the preceding issue—namely, 1s., post free 1s. 2d. from this office.

MR. G. BOLAS sends us FLOWERS OF ALLAMANDA NERIIFOLIA and HIBISCUS ROSA SINENSIS, remarking that "The two plants are grown in 12-inch pots, and have flowered most profusely from the early part of January. They are two good old plants worthy of more general cultivation. The flowers last longer in water than on the plants. The Allamanda is stopped first joint from the flowering shoot, breaks out and flowers again very shortly; the Hibiscus branches are twisted down and flower freely at every break."

THE fourth edition of the CATALOGUE OF MISS M. NORTH'S PAINTINGS AT KEW is just to hand, and, apart from its merit as a descriptive list of a most remarkable collection of paintings, it is an interesting manual of geographical botany. It has been compiled by Mr. W. B. Hemsley, and contains a map of the world, showing the countries and districts visited by Miss North. About 900 species of plants are represented, belonging to no less than 727 genera. *Lælia purpurea*, mentioned at page 16, is probably the well-known *L. purpurata*.

THE EXHIBITIONS AT THE ROYAL AQUARIUM.—I have just received an intimation from the Manager of the Royal Aquarium Company that the Exhibitions fixed for July 9th and 10th, and August 20th and 21st, are unavoidably withdrawn for this season, owing to the number of shows arranged to take place during the summer. I shall be obliged if you will make this announcement in the columns of the *Journal of Horticulture*.—RICHARD DEAN, *Ealing, W.*

THE LONDON CATALOGUE OF BRITISH PLANTS (G. Bell and Sons, York Street, Covent Garden, London), has for some years been a standard work of reference for collectors of British plants, as an index to British Herbaria, and as a guide in exchanging specimens. The eighth edition, just issued, giving in forty pages a list of the British Pteridogamia, Ferns, &c., is an improvement in many respects upon the preceding edition, very neatly printed and carefully revised.

PRESENTATION TO MR. W. P. THOMSON.—On Tuesday last the employés in the Royal Horticultural Society's Garden at Chiswick met together in the Council Room to present to Mr. W. P. Thomson, foreman in the plant department, a timepiece as a testimonial of their esteem in view of his approaching marriage. The presentation was made on behalf of the men by Mr. J. Barry, and suitably acknowledged by Mr. Thomson.

EXHIBITION OF TULIPS AT HAARLEM.—At the present time there is in the nursery grounds of Messrs. E. H. Krelage & Son, Kleinen Hontweg, Haarlem, Holland, a splendid Exhibition of late Tulips in flower, which will last to the end of this month. In a spacious tent two beds of Tulips are planted, including all the best old Dutch sorts of late Tulips (*Violettes*, *Roses*, and *Bizarres*), 700 bulbs in each bed, all different. The tent is also well decorated with flowering and ornamental plants. A gallery connects this tent with another one containing the collection of Flemish late Tulips (only *Violettes* and *Roses*), bought last year by MM. Krelage at Lille from Mr. Jules Lenglard, the last good collection existing there. There are two beds arranged alike, each containing 840 sorts. Probably such a large exhibition of late Tulips has never been seen before. In 1885, after more than twenty-five years' rest, Messrs. Krelage again opened their Tulip show, which is now repeated on an extended and improved scale.

MR. STAVELEY TAYLOR writes in reference to ripening GRAPES AFTER CUTTING—"I shall be glad if you, or any of your readers experienced in Vine growing, can tell me if there are any means by which Grapes cut from the Vines when they are only half or two-thirds ripe can be ripened in a dwelling house. Would they mature if put into bottles and kept in a warm room?"

THE ABBEY PARK, LEICESTER.—This extensive and admirably laid out Park richly deserves a visit from all interested in landscape gardening, and who can admire excellent spring and summer bedding, and the 3rd of August will be a special day, as a horticultural exhibition on a large scale is to be held there. A very extensive display of early Tulips and other spring bedding plants has been seen there this spring, but it is the summer bedding which is the great feature of the Park, and in which Mr. J. Burn uses a great quantity of succulents, having one of the finest collections in the kingdom.

IN the *Midland Free Press* of the 15th inst., a Leicester paper, we notice the following:—PRESENTATION TO MR. J. BURN.—The thousands who, during the winter months, had the pleasure of being present at the series of popular promenade concerts in the Floral Hall inaugurated by the Mayor, will remember with pleasure the beautiful and tasteful manner in which the platform and its surroundings were florally decorated under the direction of Mr. J. Burn, of the Abbey Park. It was felt by his Worship the Mayor and the committee of gentlemen who acted with him in the promotion of these concerts that Mr. Burn's services should in some way be recognised, and on Saturday afternoon last he (Mr. Burn) was the recipient of a very handsome silver tea and coffee service, most elaborately and appropriately chased with Fern leaves, which bore the following inscription:—"Presented to Mr. J. Burn in

recognition of his valuable services to the Committee of the Mayor's (I. Hart, Esq.) Subscription Promenade Concerts.—March 30, 1886."

— GARDENING APPOINTMENTS.—Mr. James Child, late head gardener and bailiff to Mrs. Torr, Garbrand Hall, Ewell, has been appointed head gardener and bailiff to W. Bailey Hawkins, Esq., Houndswood, St. Albans. Mr. J. Silver, late head gardener to the Right Hon. Lord Trevor, has taken the Norbury Nurseries, South Streatham, S.W., lately in the occupation of John Parker & Sons, where he intends carrying on the business of a nurseryman, florist, seedsman, and hardy herbaceous plant grower. Mr. Wm. Wenman, after having been foreman at Hickleton, Doncaster, for six years, has been appointed to take charge of the gardens there, succeeding Mr. Harris.

— THE Committee of the PRESTON AND FULWOOD HORTICULTURAL SOCIETY with a number of friends met together on Saturday evening, May 15th, for the purpose of presenting Mr. Atherton, the Hon. Secretary, with a most beautiful drawing-room timepiece, also for Mrs. Atherton a tastefully hand-painted tea and coffee service in china, in recognition of his much-valued services. Mr. Atherton has worked hard for the Society for upwards of seven years as Secretary, for which he has received nothing more than an annual vote of thanks. J. Garlick, Esq., J.P., very kindly consented to preside and make the presentation, which he did with a few well-chosen remarks. Mr. Atherton replied, expressing his sincere thanks to those present. Mr. Swan and others remarked that Mr. Atherton well deserved the presents, also continual sympathy from the members at all times.

— THE usual monthly meeting and conversazione of the Horticultural Club took place on Tuesday last, when there was a good attendance of members, including Messrs. Cousens, Girdlestone, Geo. Paul, J. D. T. Llewelyn, H. J. Pearson, C. Pearson, Wheatstone, Professor Sanders of Ontario, Canada, P. Crowley, &c. The discussion was opened by an interesting paper on the Bog Garden, by Mr. Geo. Paul, who detailed his experiences at High Beech, and gave many interesting illustrations of the mode of making one, and of the plants which had succeeded or failed. The paper appears in another column. The discussion was continued by Messrs. Llewelyn, Cousens, E. Jenkins, Professor Sanders, and others, and many interesting facts were elicited. A cordial vote of thanks was unanimously given to Mr. G. Paul for his interesting paper.

— THE monthly meeting of BELGIAN HORTICULTURISTS was held in Ghent on the 10th inst., the following being present:—MM. Moens, Closon, Hye-Leysen, Em. Decock, B. Spae, Ch. Van Geert, Cuvelier, Rosseel, Desmet-Dnrvier, Blanquaert, Arth. Desmet, Peeters, A. Van Geert, père. M. Moens presided, and Jules Closon was Secretary. Certificates of merit were awarded for *Odontoglossum Alexandræ* var. *Helenianum* from M. Halkin of Brussels; *Davallia foeniculacea*, from M. Aug. Van Geert; *Rhododendron hybridum*, *The Strategist*, from M. B. Spae; *Masdevallia Chelsoni*, *Cypripedium microchilum*, and *Cypripedium Curtisi*, from M. Hye-Leysen. A cultural certificate was awarded for *Ptychosperma Alexandræ*, from M. Emile Decock, and honourable mention for *Cattleya Mossiæ* var., from Madame Veuve Van der Swaelmen; *Pescatorea cerina* var., from M. Louis Van Houtte; *Impatiens Sultanii* aureo-variegata, from M. Aug. Van Geert; *Tillandsia hieroglyphica*, from M. Louis Van Houtte; and *Dendrobium thrysiflorum*, from M. James Bray.

### AMERICAN BLACKBERRIES.

ALLOW me to add my testimony to that of "A Kentish Gardener." I also bought a dozen of the advertised plants with a still worse result: not one survived. I doubt if the dried-up twigs I received were in a condition to grow.—A DORSET PARSON.

As requested by a correspondent in your last issue, I give my experience of the much-advertised variety of the American Blackberries. I ordered a dozen. Each had a single stem, except one, which had two, of about a foot in length, and of the thickness of a quill. Seven are dead, two are weakly, and three are growing well, though still small, in fact about the size of a small Gooseberry bush.—W. R.

WE have read that in certain trades when the public demand is abating, adverse criticism is brought to bear upon the articles that the dispensers are desirous of ridding themselves, purposely to again awaken the public interest, so that the parties who have the goods to dispose of can advertise the same gratuitously. In case, therefore, such a reflection should be brought to bear upon the subject of these remarks, we can

readily answer the Editor and the readers of the *Journal of Horticulture* that such is not the case in this instance.

In reply to "A Kentish Gardener," we may observe that when we introduced the Wilson Junior into this country we were not oblivious of the difficulties in the way of establishing the culture of this American Blackberry here. Of course, the primary obstacle is transit. To cover this point we undertook to replace any plants that might fail, and advised "A Kentish Gardener" and other purchasers of our willingness to do so, fully knowing the value of what we were introducing. The first importation that we received was in the spring, 1885, and being delayed by the severe and late frosts on the other side, did not reach us until April, and on arrival were distributed far and wide at once.

May we suggest to "A Kentish Gardener" that before he imputed an attempt at imposition (!) he should, in common English fairness, have written for an explanation and rectification? Had he done so—agreeable with our circular sent to him—we should have willingly replaced the canes that had failed. There are, of course, other contingencies, such as prejudice, &c.; but notwithstanding them all, we predict, and with good reason, that in less than ten years the Wilson Junior, along with some other seedlings we are raising, will be known and appreciated throughout the country.

We are well aware that all this correspondence serves to indirectly advertise us, and although not at all desirous of abusing the privilege kindly afforded us by the Editor, we consider it only right to reply.—VICCARS, COLLYER & CO.

[The last paragraph in a printed circular sent with the above communication contains the following sentence:—"We undertake to replace any plant that may happen to fail." Purchasers now know what to do, and there appears no longer any necessity for prolonging the discussion on this subject.]

### BEDDING OUT.

THE hedding-out time is a busy and anxious one in many places. The business is caused by the work of planting many hundreds or thousands of plants, and the anxiety is produced lest frost or adverse weather should come and injure them. In some parts of the south we have planted the whole of our flower beds in the second week in May, but further north we were afraid to do this, and deferred operations until the middle of May. From the middle of May to the commencement of June is a safe time to bed out in most districts, and with good plants and care the beds will soon be furnished with abundance of foliage and a profusion of blossom.

The most important matter of all is to have the plants well hardened off and quite accustomed to the open air, especially at night, before they are placed in the beds. No plants can be expected to be an immediate success that are brought out from a warm humid atmosphere under glass, placed in cold soil and under the influence of a drying wind or hot sun. If there is not enough of space under glass to allow the plants being propagated early and hardened in good time it would be better to give up bedding of this character. Where, however, the plants were propagated from seed and cuttings in March, kept moderately warm until the middle of April, and then gradually withdrawn from the heat until they were in the open air altogether early in May, there will now be no danger of their being checked.

Golden Feather, *Calceolarias*, and similar plants should be placed out first, *Pelargoniums* may follow, but *Dahlias*, *Alternantheras*, *Tuberous Begonias*, and other plants which are easily checked should be left until the last. By following a system of this kind we place out many hundreds of plants annually without ever having any blanks to fill. Before any attempt is made to lift the plants from the box in which they are growing, or turn them out of the pots, the soil should be thoroughly saturated at their roots, then each plant will be transferred with a good quantity of soil attached to the roots. Small plants for carpet beds can often be planted with the hand, merely making a small hole with the two fore fingers and pressing the soil back again; but any too large for this should be planted with a trowel. No matter what size the roots may be, the hole for their reception should always be a little larger, so as to admit them freely. We have had some men planting who made the holes very shallow, and after the plant was in they pressed the roots down hard, which broke many of them as well as loosening all the soil about them. All plants with long stems must be planted deeply, and those with rather long top growths should be planted on their sides. *Petunias*, *Verbenas*, and Ivy-leaved *Pelargoniums* are amongst these, and as soon as they are planted they should be pegged down. As a rule wet weather is preferred for planting, as it agrees best with the plants and saves watering. One thorough watering after planting is more beneficial than repeated surface sprinklings. When the soil has been watered once and is getting dry again, the Dutch hoe should be run through it to break up and level the surface, and a hoeing now and again during the season is all the attention they require to keep them in good condition.—M.

### THE MAKING OF A BOG GARDEN.

[A paper read by Mr. George Paul at the Meeting of the Horticultural Club, Tuesday, 11th inst.]

GIVEN—you have a piece of squashy, water-charged bog land, on which you dare not tread for fear of going in over your shoetops, worthless except to produce a few Rushes, and maybe an Alder or Willow stub—Can it be made into an attractive garden? YES—but it takes two or three years to do it, to get rid of its old indwellers and fully establish the new-

comers, and to find out what will and what will not do, for I do not think we know very much about the likings of moisture-loving hardy plants.

#### THE SITE.

My experiment was tried at High Becch, and this is how the hog garden was made. The site was one of those depressions which are found on the Bagshot Sand hilltops, upon the Wimbledon, Epping Forest, and Hampstead Heathlands. Between two ridges of raised ground and on the falling slope occur spewy springs issuing from the higher ground above, and soaking down the hollow, widening and gathering moisture till the water issues in a small rill at the bottom of the decline. *Droseras*, Ivy-leaved *Campanula*, and other native bog plants are found with the sphagnum and rushes in the wet springy ground.

The successful growth of *Sarracnias* and *Dionæa* first led to carrying out the idea more fully. There are many hardy plants which from the want of the continuous moisture of such a site, and which they enjoy in their native haunts, do not succeed year after year in the ordinary herbaceous or garden border; a hot summer comes and they are not—to instance some *Calthas*, the double sorts of the glorious Marsh Marigolds now brightening our Lea Marshes, *Sarracnias*, Primroses from Himalayan bogs, *Spiræas*, and others. The idea was to show these plants in their natural way, and so to see them in their full beauty.

#### HOW BEST TO USE THE SITE—REQUIREMENTS.

The chief thing to do was to husband and use thoroughly the water running into and accumulating in the bog. A temporary deep drain was made right up the centre, and the work was done in a dry early autumn, allowing the men to move on the surface. This, husbanding the water, was done by forming beds following the circular shape of the depression, and so made that the upper set received all the issuing spewy springs that could be found issuing from the surrounding banks on to the surface of the bog. A 2½ feet wide bank of clay was then put in and trodden firmly on the lower side of the beds, defining the beds and keeping the moisture in them until allowed to escape.

A second series of beds was a foot lower. A third a few inches below this, and one bed of this series had all the peat removed until the clay which (except here and there where water oozed up through clayey sand) formed the bottom of the bog, was reached, thus making a small pond to receive the overflowings from the upper beds. A fourth series of beds received the overflow from the pond and upper beds, as well as one or two independent springs from the sides, and eventually the water ran off into the brook or ditch in a small clay-lined channel built across the so to speak miniature valley.

The small difficulties I had to overcome were in making the clay walls to the beds. Towards the sides of the hollow a firm bottom was found, but when the bottom was springy the water simply oozed up through the clay and does so more or less still, but the dams or walls do their work—that is, they keep the moisture in the several levels well. They act also as paths to let you walk in comfort about the space (which, by-the-by, is 60 feet square), the chief thing to make a hog garden useable and enjoyable in all weathers and seasons. But the paths at first did not answer, for you found yourself up to the knees in miry clay. A surface crust of gravel and cement concrete was tried, but the water sponged up through it, the clay swallowed it; so something had to be done to keep the clay down and get a safe path.

The foreman suggested, and a wood clearing close by furnished, the remedy. For the spewy places some small Beech trunks were split in two, laid round side downwards along the paths, and short split branches (smaller) were laid across them, making corduroy paths 2½ feet wide. A little gravel between the logs keep them in place; they are a perfect, comfortable, and lasting path, and keep the clay down and in place. I forgot to say that from each series of beds water above a certain level flows in small drain pipes into the next level, enabling the height of the water in each bed to be regulated.

In the middle of one or two of the largest central beds an upright post is driven, the top just on the surface, to receive the one end of three split trees, and so allow every plant in the bed to be reached. So far we have gained control of the water, enlarged and retained the full hoggy space, and have means of moving comfortably about the moist area.

#### PREPARING THE BEDS FOR PLANTING.

Owing to enlarging the area there was not sufficient peaty material. foreign peat and leaves had to be furnished to make 1½ foot of good soil in each bed. Small rills drawn with a hoe to the mouth of the overflow pipe allow the bog to be controlled, a stroke of the hoe retains moisture, or allows the surface and crowns of the plants to be kept dry or raised out of the water. The beds are sub-divided by small peat banks, on which plants liking their toes or root-extremities in water, but their crowns to live in drier regions, are fixed.

The chief enemies have been, the principle of the "fittest surviving," in the shape of the rushes and water-loving grasses striving to resume possession, an occasional and timely weeding conquers this, the Liverwort tries to surface the whole, to the detriment of the smaller plants, such as *Soldanellas*, *Vio's*. It wants a careful, and now and again, scratching away. The birds, tempted by the loose peat surface, after hoeing or weeding, come and scratch for food, and some smaller winter-resting plants, such as *Dionæas*, *Droseras*, *Pinguicula*, are apt not to be forthcoming when looked for next spring. Just a word as to full exposure to sunlight. The space is open, except for a slight shade in the shape of a row or two of 6 feet Hollies to the south, but my experience is that moisture at the roots, few plants object to this. In this the garden differs

from Mr. Wilson's interesting experiments at Wisbey, where many of the plants are under, or shaded by overhanging trees. In other ways our experiments differ, besides it is not everyone can devote a week to gardening.

#### THE PLANTS.

Of the plants first put in, there were many died. The water supply of the several parts was unknown; some were drowned, some were too dry. The best survivors of the first plantations are—*Calthas*, double forms, the monstrous, the *Palustris plena*, and the later dwarf and double form. Of the *Sarracnias*, purple flowers and seeds freely about. *S. Drummondii* is the next hardiest. *S. flava*, *S. rubra* and *psittacina* seem to live, but get weaker after each winter. I am sorry that some interesting hybrids sent me by Mr. H. Veitch and Mr. Wrigley have not survived. The white *Pilewort* is a splendid plant in the bog. *Lobelia syphilitica* and the American *Osmundas* flourish well together. On an extreme jutting out into the small pond *Saxifraga cordata* flowers gloriously, the golden *Lysimachia* has to be restrained, or would cover the surface. The striped *Viola* and *V. pedata*, *Ranunculuses*, including the beautiful little one, *Parnassifolius*, thrive. *Dondia Epipactis*, *Valeriana Phu aurea*, the *Trollius*, and more especially the varieties of American Cowslip, *Dodecatheon Jeffreyanum*, and others are quite at their best.

Of the taller-growing plants the *Thalictrums*, *Achillea Parmica* fl.-pl., the American *Liatris*, *Lysimachia clethroides*, *Lychnis* of sorts, *Gentiana pneumonanthe* and *macrophylla* thrive freely. *Pyrola rotundifolia*, the *Mandrake* with its curious two-legged roots, *Pyrola rotundifolia*, *Trientalis europæa*. On the slightly raised banks the Arctic Bramble and the *R. Chamæmorus* have established themselves, and fight where they join for supremacy with the American Cranberry from the Wishey wood. *Droseras*, *Dionæa*, and *Pinguicula* have been disturbed this winter by the birds. *Orchis foliosa* seems to rejoice in a water-teeming bed, and is there quite hardy. No doubt other *Orchis* would succeed.

*Primulas* have a hed to themselves, forty or fifty of the Alpine and Himalayan kinds were planted, but probably from the want of limestone or from not having been planted on shaly slopes charged with water, only the following have survived and thriven. *P. japonica* and *denticulata* are becoming the self-sowing weeds of the garden. *P. rosea* and its large-flowered variety, *P. Wulfeniana* and the varieties of *minima*, *P. viscosa nivalis*, *glutinosa* need also shade; *P. villosa* and *Stuartii*; *Munroi* needs the moistest place. A large bed is given up to *Spiræas*, such as *Aruncus*, *palmata*, and *japonica*, they are mixed with the American Lilies of the *pardalinum* type, which attain 6 to 8 feet. Mr. Bull's *Astilboides* and the white form of *Palmata* thrive apace.

The *Zehra* and corkscrew rushes need to be kept in bounds. Of *Irises*, I took counsel with Professor Foster; the stronger varieties of *Iris Kæmpferi* are at home in the wet bog, but occasionally a sort disappears in winter. They seem quite at home in the clay banks of the rill.

I should occupy too much time if I gave all the failures; the result of the experiment has appeared to be a success. If my remarks lead some others to make a trial in this direction I shall be glad. So many have more experience than I have had. Will they tell us something about it?

### THE HEREFORDSHIRE POMONA.

#### PRESENTATION TO MISS BULL AND MISS ELLIS.

The invaluable services of Miss Bull and Miss Ellis of Hereford, in painting the original drawings for illustrating the "Herefordshire Pomona," were to some extent recognised by a testimonial presented last week. Throughout his great work the late Dr. Bull was encouraged by Lady Emily Foley, the rich and fruitful gardens of Stoke Edith House being ever open to the Woolhope Naturalists' Field Club; and it was with her ladyship that the idea originated of making the presentation under notice. (It was also, we may mention, through her ladyship that Her Majesty the Queen commanded a copy of the "Herefordshire Pomona" to be specially prepared for the Royal Library at Windsor.) About eighty of the nobility, gentry, and professional gentlemen subscribed, and the testimonial to each lady took the form of a miniature portrait on ivory of the late Dr. Bull, together with a cheque of 100 guineas. The interesting ceremony took place in the drawing-room of the Deanery, and many of the subscribers were present.

The Dean said he should be interpreting the wishes of those present if he asked Lady Emily Foley to make the presentation. Mr. Henry Higgins seconded the proposition, which was supported by Mr. Piper.

Mr. Reginald Symonds, the Hon. Secretary, intimated that several letters in explanation of inability to attend had been received. Dr. Hogg, in his letter addressed to Lady Emily, said that after the considerable share he had taken in conjunction with the lamented Dr. Bull in the preparation of the "Herefordshire Pomona," it was a great disappointment to him not to be able to be present on such an interesting occasion. It was very gratifying to him to know that so substantial a recognition of the devoted services Miss Bull and Miss Ellis had rendered not only to their county, but to their country, by their illustrations to the "Herefordshire Pomona," which far excelled anything of the kind produced in England, and which were in no way inferior to the efforts of the best artists of the Continent, had been secured. The other letters were from Lord Bateman, Sir William Vernon Guise, Mr. Pulley, M.P., Mr. Rankin, Mr. W. Henry Barneby, Mr. B. St. John Attwood-Mathews, Mr. Edwin Lees, Worcester; Mr. E. Caddick, Birmingham; Mr. Arthur Hutchinson, Rev. Prebendary Phillott, Rev. C. H. Bulmer, Rev. J. E. Vize, Welshpool; Mr. James Davies, and Mr. C. Rootes.

Lady Emily Foley then read the following address, and gracefully made the presentation:—

"The 'Herefordshire Pomona' having now been completed, the Woolhope Naturalists' Field Club, under whose superintendence it was brought out, and the ladies and gentlemen whose names are appended, from a wish to

manifest their appreciation of the artistic ability and devotion displayed during eight successive years by Miss Bull and Miss Ellis, who painted from Nature, solely for the love of art, the original drawings for the necessary illustrations, have great pleasure in requesting each of these ladies to accept a miniature portrait on ivory of the late lamented H. G. Bull, Esq., M.D., the learned general editor and originator of the work, together with the sum of 100 guineas, in recognition of their eminent services in the production of a book which has justly been styled by the distinguished pomologist, Robert Hogg, Esq., LL.D., F.L.S., London, 'the most splendid work in artistic execution, and fidelity in design, which has ever been produced on the subject.'

The signatures appended to the address were those of the following:—Lord Bateman, the Earl of Powis, Lord Windsor, Hon. and Rev. B. L. Scudamore-Stanbope, Lady Croft, Sir William Vernon Guise, Elmore Court, Gloucestershire; Mr. Pulley, the late Dr. Bull, Mr. Arthur Hutchinson, Mr. T. B. Acton, Grove Road, Wrexham; Mr. B. St. John Attwood-Matthews, Mr. R. W. Banks, Mr. W. H. Barneby, Mr. Thomas Blashill, Mr. J. A. Bradney, Rockfield, Monmouth; Rev. C. H. Bulmer, Rev. C. Burrough, Mr. E. Caddick, Birmingham; Alderman Cam, Rev. Canon Capel, Abergavenny; Mr. T. Carver, Mr. Joseph Carless, jun., Dr. Chapman, Burghill, Hereford; Rev. G. H. Clay, Aston Rectory; Rev. Prebendary R. H. Cobbold, Mr. E. W. Colt-Williams, Mr. James Davies, Major Doughty, Rev. W. D. V. Duncombe, Rev. Canon Dupont, Denver Rectory, Downham; Dr. Glendinning, Abergavenny; Mr. E. H. Greenly, Rev. Prebendary F. T. Havergal, Ross; Mr. Henry Higgins and Mrs. Higgins, Thinghill; Dr. Robert Hogg, Rev. E. J. Holloway, Clehonger; Mr. John Hopton, Rev. Michael Hopton, Mr. W. J. Humfrys, the late Reverend W. Jones Thomas, Llanthomas; Mr. John Lamb, Lady Emily Foley, Lady Henry Somerset, Lady Hindlip, Hon. and Very Rev. George Herbert, Dean of Hereford; Rev. Sir George Henry Cornewall, Sir Harford J. J. Brydges, Miss Hutchinson and Miss Charlotte Hutchinson, Hagley Park; Rev. W. H. Lambert, Mr. Theophilus Lane, Mr. Edwin Lees and Mrs. Lees, Green Hill Summit, Worcester; Rev. A. Ley, Sellack; Mr. James W. Lloyd, Kingston; Mr. J. H. B. Lintley, Mr. C. G. Martin, Mr. J. J. Merriman, South Kensington; Mr. H. C. Moore, Mr. J. Griffith Morris, Mr. T. C. Paris, Hereford; Mrs. Pateshall, Mr. C. H. S. Percival, Longwiton Hall, Morpeth; Mrs. Robert Platt, Staleybridge; Rev. Prebendary W. H. Phillott, Mr. G. H. Piper, Rev. D. Price, Little Marcle; Mr. J. Rankin, Very Rev. Prior Raynal, St. Michael's Priory, Belmont; Mr. J. Riley, Putley Court; Mr. C. Rootes, Mr. J. F. Symonds, Rev. W. S. Symonds, Pendock Rectory, Worcestershire; Rev. F. H. Tatham, Mr. Vachell, Cardiff; Mr. R. V. Vassar-Smith, Charlton Park, Cheltenham; Rev. J. E. Vize, Forden Rectory, Welshpool; Mr. J. G. Woodhouse, Mr. J. H. Wood, Tarrington House, Ledbury; Mr. R. F. Woollett, The Mount, Newport; and Mr. H. C. Beddoe.

Mr. Higgins said he was requested by Miss Bull and Miss Ellis to express their warmest thanks for the testimonial which had been given to them. Having discharged that duty, he could not but say how much they were indebted to those ladies, for it was a fact that if Dr. Bull had not secured the gratuitous services of Miss Bull and Miss Ellis, they would never have had that beautiful work; it would have been too costly a book to have engaged professional artists. In obtaining the gratuitous services of these ladies Dr. Bull was able to carry out his work, and, therefore, they were greatly indebted to them. But not only that, it was a great thing for two young ladies to spend eight years of youth in a public work of this character. He thought it was very commendable when two young ladies came forward and devoted themselves to the public work of this character, and it was a thing which they ought to recognise in the way they had done.

Mr. G. H. Piper observed that it was due to them to return a vote of thanks to Lady Emily Foley for so kindly and gracefully making the presentation. He made the proposition to them in his official character as President of the Woolhope Naturalists' Field Club, which, as far as the powers of its members would allow, assisted in bringing out the "Herefordshire Pomona," the completion of which they then celebrated by making that appropriate presentation to Miss Bull and Miss Ellis. The work had been successful from beginning to end, and the presentation crowned the efforts of those ladies who assisted in producing it. He proposed a vote of thanks to Lady Emily.

Mr. C. G. Martin (the retiring President of the Woolhope Field Club) seconded the proposition, and, in doing so, said he did not quite agree with Mr. Higgins as to its being absolutely necessary that they should have had gratuitous help. Those who thought so seemed to forget the wonderful fertility of resource of Dr. Bull. If he had not been favoured with the services of these ladies, he would certainly have devised some other means to carry out the object upon which he had set his heart. However, they were deeply indebted to Miss Bull and Miss Ellis for their services.

The Dean said that on behalf of Lady Emily Foley he thanked them for the compliment they had paid her. He assured them that it had given her ladyship very great pleasure to attend on that occasion. Her ladyship, like them all, had greatly admired the beautiful illustrations of the "Pomona" which were due to the skill, the artistic skill, of Miss Ellis and Miss Bull, and she also joined with them all in remembering their late lamented friend (Dr. Bull) with the greatest possible respect. He again assured them that it had given her ladyship great pleasure to attend on that occasion.—(*Hereford Times*).

#### DEATH OF M. AMBROISE VERSCHAFFELT.

MANY of our readers will regret to hear of the death of M. Ambroise Colette Alexandre Verschaffelt, better known perhaps by his familiar name of M. Ambroise Verschaffelt of Ghent, which occurred on the 16th inst. at his residence, 98, Chaussée de Courtrai. M. A. Verschaffelt was one of the most prominent of the great Belgian nurserymen, and his name was as "a household word" throughout the world of horticulture. The founder of the vast establishment now directed by M. L. Linden in the Rue de Chaume, he there carried on an extensive trade for many years, till he relinquished it in favour of M. J. Linden, who was at that time in business at Brussels. Since then M. Verschaffelt has lived in retirement, though not in idleness, for he still retained his love for horti-

culture, and occupied his leisure in cultivating those plants which commended themselves most to his horticultural tastes. For a considerable time M. Verschaffelt has suffered from a painful malady—we believe cancer of the tongue—to which he succumbed. He was the founder of "L'Illustration Horticole," and besides holding many honorary offices in Belgium he was officer of the Order of Leopold, was decorated with the "Croix-Civique" and the following orders:—St. Maurice and Lazare, the Legion of Honour, St. Anne of Russia, the Medjije, Frédéric of Wurtemberg, the Lion of Zœbringen, Adolphe of Nassau, Grand Duke of Hesse, and the Dukes of Nassau and Oldenberg. M. Verschaffelt was born at Ghent on the 11th December, 1825, and was consequently in the sixty-first year of his age.

#### ORCHIDS AT THE GLEN, LEWISHAM.

If any persons still doubt that Orchids can be successfully grown in town or suburban gardens, a visit to Dr. Duke's collection at The Glen, Lewisham, would speedily dispel the illusion, and would, moreover, convince the most sceptical that the mysteries with which some invest the culture of Orchids are purely imaginary. The garden is a small one, such in fact as is found attached to most suburban residences about the same distance from the city, yet by a careful economy of the space at command about ten small houses have been erected near the boundary wall, still leaving space for a miniature lawn, rockery, and flower garden. The collection of Orchids is a remarkable one in several respects. The number of species and varieties is large, much larger than is the case in many more elaborate and extensive establishments. The condition of the plants also is most satisfactory, healthy growths and abundant flowers being the rule, with extremely few exceptions, the result of the adoption of a consistent reasonable treatment. High temperatures are abjured at The Glen, free ventilation at all times except when the weather is severe, and full exposure to light, affording only sufficient shading to break the force of the sun's rays when most powerful, are the guiding principles of practice, and any that might be disposed to dispute them would find an irresistible reply to their strongest arguments in the plants themselves. They grow vigorously, flower freely, and afford every indication that the treatment they receive is exactly to their liking, and what more can be needed?

Within five years Dr. Duke has formed a collection of which he has every reason to be proud, and the pleasure he derives from watching the progress of his favourites is ample recompense for the trouble and expense incurred. By purchasing established plants of known varieties, or choice varieties, and occasional lots of imported plants, the character of the collection has been steadily improved, and at the same time the interest of expectancy has been increased by the gradual flowering of the imported plants. Sometimes a grower has the satisfaction of finding a good variety amongst many that are of little value, but this is quite sufficient reward for the watching, although the actual pecuniary gain may not be great. There is no doubt that the mild excitement attending the expectation of securing a prize from imported plants has tended to increase the attendance at the sale rooms, but established plants of known value can now be procured so cheaply that most of the best collections are formed mainly of them, the others coming in as supernumeraries.

One of the principal houses at The Glen is that devoted to Cattleyas, which is a light and lofty structure with a sharply inclined roof, and seems to suit the plants admirably. It is a cheaply constructed house, with a light wooden framework glazed down to the side stages, and below these to near the ground level the framework is covered with Willesden paper, a waterproof composition that has proved very durable and quite effectual during the past severe season. A space of about 2 inches is left between the lower margin of this and the wooden frame, extending the whole length of the house, so that constant ventilation is provided, and it was only found necessary to close this for a short period when the frost was sharpest and the wind keenest. There is a small lantern at the apex of the house, and a space is similarly provided there which is almost constantly open. Further means of ventilation is afforded by hinged or moveable boards at the sides of the house. The doors are left open daily in fine weather, and altogether the plants are nearly as much exposed during the warmer months of the year as if they were outside. One very remarkable result of this is seen in the purple hue the leaves and even the pseudo-bulbs have assumed, which we have never seen so strongly developed. Many species of Cattleya and Lælia are included in this house and look equally thrifty, large numbers of sheaths now showing promise a beautiful display a few weeks later. For shading a light canvas termed Willesden scrim is employed, which, while it efficiently prevents the sun scorching the foliage, it admits abundance of light. Shingle is employed for the stages in preference to the small coal now used in many establishments, or the broken shells which are equal favourites with others; but the stones are found to answer satisfactorily in preserving the moisture. They at the same time keep clean, do not provide a harbour for insects, and have a neat tidy appearance. In some of the houses the corrugated zinc that has been repeatedly recommended is used in the place of either wood or slate for shelves, for which purpose it has much to recommend it. Another point observed at The Glen that is also studied in other establishments is to have the floors of earth, both the paths and beneath the stages, for a more steady supply of moisture is thus afforded than from brick, tile, or stone floors. Success with Orchids, as in other departments, depends in a great measure on attention, to these apparently small matters.

Near the Cattleya house is a range of small houses, some of which might almost be called diminutive, yet in one or two of these devoted to the Orchids in flower is a display that could not well be surpassed in

the same space. *Cypripedium*, *Cattleyas*, *Laelias*, *Epidendrums*, *Lycastes*, the late-flowering *Calanthe Regnieri*, *Oncidiums*, *Cymbidiums*, *Odontoglossum vexillarium*, *Dendrobiums*, *Galeandras*, and innumerable others. Perhaps the most striking of all is, however, the lovely *Oncidium Marshallianum*, which is bearing its handsome panicles of golden flowers in profusion, one variety being very notable for its rich deep colour. *Oncidium concolor* also is freely employed. These are arranged with miscellaneous flowering and fine-foliage plants to form a bank on one side of the path with a few on the side also, but the space will not admit of grouping on both sides in the same way. The plants are very tastefully disposed, and we have never seen such a pretty effect produced in a small compass. In a house beyond a good collection of *Phalenopsis* is grown,

*O. cirrhosum*, *O. maculatum*, and *O. luteo-purpureum* being similarly well represented. Communicating with this house is a large frame in which *Disas* are successfully grown. Near by is a small house, very little more than a glass case, where the *Barkerias*, for which Dr. Duke is famed, are thoroughly at home in baskets or upon blocks. They are suspended near the glass, and with abundance of moisture during growth, and a good season of rest, they flower most freely every year.

There are two other houses devoted to miscellaneous collections of Orchids, but they do not need special reference now. It must suffice to conclude these notes for the present that the Orchids at The Glen are in every way a credit to their owner, and the collection must be ranked as one of the best of those in the suburbs of London.—L. C.

Fig. 73.—DR. DUKE'S ODONTOGLOSSUM TRIUMPHANS. (Half natural size.)

mostly small plants at present, but advancing well, suspended near the glass with a general collection of *Anthuriums* and other stove plants.

A house is devoted to *Odontoglossums* and other "cool Orchids," the varieties of *O. crispum* being especially good, several having large, round, beautifully formed flowers, pure white, and deeply tinted with rose. *O. triumphans* is also a favourite, the varieties of fine quality, and one, that represented in fig. 73, is exceedingly good. Dr. Duke has some of his best varieties sketched in colours on plates or "plaques," for suspending in rooms, and that from which the engraving was prepared was thus depicted of its true size. In the woodcut it has been necessary to reduce the size one-half, the original flower measuring 5 inches in diameter from tip to tip of the petals. The colours also were very rich, a fine deep yellow tint and bright reddish-brown blotches. Of *O. Halli* there is also an uncommonly fine variety; the favourite *O. Rossi majus*, *O. Cervantesi*,

#### FRITILLARIA MELEAGRIS.

FROM a remark made by a friend, I have been led to send you a note of a display of flowers to be seen in this neighbourhood, which might very properly be termed one of Nature's flower shows. This occurs in a meadow on the estate of Lord St. Germans and consists of about five acres of *Fritillaria Meleagris*, the white and the purple forms being about equally distributed. In the sunshine the gleam of colour, though modest, can be seen at some distance, and when amongst them it is difficult to walk without treading upon them. A thin undergrowth of *Cowslips* adds to the beauty of the sight. From the cottage to the mansion there is scarcely a home but which is decorated with them, numbers also being used in the making of wreaths and crosses to place on the graves of departed friends. The remark of my friend was, "It beats even the

London parks," but upon that point I am not in a position to pass an opinion.—J. COPSON, *Down Ampney*.

### A DAY IN THE COUNTRY.

"NOTHING novel in this," may well be muttered by gardeners and readers of garden literature who spend the greater part of the time in the open air, far from the "madding crowd;" but are there not gardeners even who spend week after week "within the walls," where the softened, heated air becomes oppressive, and "under glass," where the temperature is exhausting, who would not enjoy a day in the country now and then, and feel refreshed by the exhilarating breezes from the hills or the ocean? Without a doubt there are. But there are gardeners and lovers of gardens, the greater part of whose time is spent, not in the country but in the environs of towns, and some even in the heart of the greatest city in the world. These are they who enjoy an escape from the noise of ever-revolving wheels and clatter of hoofs, the rush and the hum of the seething multitude, jostling together in the multifarious duties of life; and of such I am one.

My "day in the country" was very like a whirl; a case of being "on the move" from 6 A.M. to 12.30 P.M. through eight counties—Worcestershire, Gloucestershire, Warwickshire, Staffordshire, Oxfordshire, Berkshire, Buckinghamshire, Middlesex, and home again to Surrey. But I started overnight, and rested for the coming day in a quiet parsonage. It was the result of a letter to this effect:—"If you can leave Paddington at 1 P.M. on Tuesday and hook to Leamington I will meet you there, and if fine, drive you here through some of our most charming Warwickshire scenery." The invitation was irresistible; the "here" referred to in it was Alderminster; the writer the Rev. J. A. Williams. Mr. Williams is widely known in the Rose world, not so much as a great exhibitor, but as one of the best of the expert judges who officiate at the National Rose Society's shows; he is, moreover, a first-rate grower of Roses in his not large garden; in fact, a good cultivator generally; a hard and successful worker in parochial affairs, and has the true English gentleman's tact of making his friends at home the moment they enter his gates.

#### SPRING'S DELIGHTS.

There is, perhaps, no time of the year when an escape from town is more enjoyable than during the early days of May. Trees, half robed with foliage fresh and tender; pastures and cornfields full of green, not brown, banks sparkling with flowers, rivulets shimmering in the sunlight, and birds singing merrily all around. Dwellers in the country, or many of them, heed not these charms; the buds swell gradually and leaves unfold imperceptibly; the grass grows and flowers open in the ordinary way, the change from day to day not being sufficiently marked to receive notice, and the music of birds is not appreciated. But, hear no birds for months, and see no fields nor tree-clad hills, then take as it were a sudden bound amongst them, and spring's delights will be seen and felt in all their refreshing reality.

#### WARWICK—ANCIENT AND MODERN.

But I am at Leamington, and Mr. Williams is on the platform. "Jump in again," was the first greeting; "let's run on to Warwick, only a couple of miles, and we shall escape some dusty roads and troops of people returning from the races." A happy thought, for there is nothing more repugnant—to me, at least, however others may enjoy it—than the reckless rushing "from the races," when the roads are inches deep in dust, and the track is indicated as by a line of smoke. At Warwick, then, we arrive in ten minutes or so; and in a moment the mind is carried back to the far distant past by ancient buildings and the towers of the old castle, which was described by Dugdale as "the most princely seat within these Midland parts." It is undoubtedly a magnificent pile, and it is gratifying to observe in these days of "advanced" notions that a strong and deep-rooted antipathy exists against tampering with the ancient buildings that adorn our land. So old is Warwick Castle that its foundation is attributed to Etheldreda, daughter of King Alfred, in A.D. 915, and it was bestowed at the Conquest on Henry de Newburgh, the first Norman Earl of Warwick. We leave it on the left, pass another venerable and exceedingly picturesque building, Leicester Hospital, on the right, emerging from the town through an ancient gateway, and are fairly on our way to Alderminster. We do not travel far before a contrast is provided for a moment's reflection. From the very ancient we come in contact with the extremely modern; not that the village of Barford, embosomed in trees, appears as if built yesterday; but because one of its sons, named Joseph Arch, labourer, has ceased for a time to delve there, and, to give him his full title, has become Joseph Arch, Esq., M.P., legislator. "And what sort of a character is this Mr. Arch?" I ventured to ask of my clerical guide. "Oh, well, you know, he can make speeches, and say funny things about parsons, but I don't think he's a bad fellow after all." That was generous. "Bad fellows" ought not to legislate, yet so diverse are the minds of men that possibly not one reader of these lines believes that "only the best" are sent to serve their Queen and country at Westminster. Then I instinctively looked over the land, and saw it was not good nor highly cultivated, and felt very thankful I was not doomed to dwell in that locality with "three acres and a cow." The plan might answer with some persons in certain districts, but to advocate anything like uniformity in respect to it regardless of personal aptitude and natural resources were in the last degree chimerical, and that being so the pastoral dream will never be realised.

We are undoubtedly traversing a beautiful district, but not a rich one

yet now and then evidence is afforded that the land is capable of improvement. Much of it is cold and profitless by want of drainage and much impoverished by masses of twitch (couch). As compared with some districts where high-class farming is practised, the condition of great tracts of land in the Midlands is markedly inferior, and it cannot be satisfactory to either owners or occupiers until more capital, labour, and fertilisers are employed in its management. But we are nearing our rendezvous and find better land and better husbandry.

#### ALDERMINSTER AND ALLOTMENTS.

The village of Alderminster is a model village. Such cottages are seldom seen; they stand in pairs back from the road, covered with climbers, and the front gardens attractive with evergreens and flowers. They were built by the lord of the manor, J. R. West, Esq., and are let with good gardens attached for a shilling a week. If the peasantry here do not know who are their friends they are very obtuse and in need of sound education. They have their allotments too, and on this matter Mr. Williams must allow me to do a simple act of justice, even at the risk of according him a measure of praise which I know he does not covet. If all had done what he has carried out, persons who live by agitation would have been deprived of their weapons. He has a portion of his glebe divided into allotments, and not the worst portion either, but the best, and not distant from the village, but close to it; and not let at a higher rent than that charged to large farmers, but lower. He has also established a custom different from all others of which I am cognisant, and it answers well. It appears to be founded somewhat on that of the Emperor of China and his doctors. So long as His Majesty remains in good health he pays them well; when he is ill he stops their stipends, shrewdly suspecting no doubt they will cure him as soon as possible. Mr. Williams is no rack-renter; he does not tax his tenants on their own improvements, but exactly the reverse. So long as their plots afford evidence of superior culture the regular low rent only is charged, but when signs of negligence are apparent an extra 25 per cent. is imposed—that is, instead of paying £1, the charge is 25s. If this does not effect a cure, the land of the good cultivators is increased, those of the negligent proportionately decreased. It is not often, however, that the rent increase fails in its object, and the tenants are not slow to remind each other if they do not "look up they will have to pay the extra five bob." It is a capital idea and, as started, works well.

#### THE CHURCH AND ROSES.

Alderminster Church is a beautiful structure—a grand old English edifice that has lately been restored. It is cruciform with a massive tower in the centre, and as perfect in its proportions as can well be imagined. It is solid, substantial, and good, with nothing to offend either the ritualist or the puritan. It is ancient, the old consecration mark in the original stone, which was discovered, and is built over the inner porch, being dated, I think, 1160, and the church was assigned to the Abbot and convent of Pershore in 1193. Roses have helped in the restoration of this fine edifice. The vicar, having made himself responsible for a considerable sum, hit on the expedient of selling blooms instead of giving them away to his friends, devoting the proceeds to the restoration fund; the flowers being fine become famed and the demand great. Nor was this all, for purchasers next wanted trees, and Mr. Williams became a Rose commissioner, selecting varieties and advising on their purchase and culture. Just as giving a few cuttings has often made a florist, so has the selling of Roses for a church made rosarians. The vicar deserves a rich harvest this year—but the winter has handicapped him—for he is working hard to accomplish his object in liquidating the claims in respect to the restoration of the fabric that has been so thoroughly renovated and which is answering its high purpose so well.

#### MR. WILLIAMS' GARDEN—ANEMONE APPENINA.

Mr. Williams does not reside at the vicarage, which is too small for a family man, but at Alderminster Lodge, a more commodious and very pleasant residence, built by the late vicar, who evidently possessed taste in planting trees, for handsome specimens of Cedars of Lebanon and other Conifers, with Purple Beeches, a Mulberry and other kinds, including a towering Lombardy Poplar, standing like a sentinel from a base of shrubs, appear to great advantage. Yews have also been disposed, so that when large enough they could be, and are, clipped to form screens and arches, thus at once being useful and ornamental. The lawn slopes some fifty yards southward, then suddenly dips to the boundary walk on the north bank of the Stour, and beyond the little but occasionally active river is a flat and beautiful expanse of country, many acres of which are occasionally submerged, the house and ground remaining high and dry on the eminence above. The garden was gay with bright beds of Tulips; but these were passed as very familiar types of beauty to horders of flowers of a different character and altogether lovely—great masses of *Anemone appenina*, having thousands of *Cineraria*-like bluish grey flowers, some of them 2 inches in diameter. It is not easy to imagine anything more lovely than a score of these on stems nearly a foot high from loose cushions of soft green leaves. But what is the secret of the vigour of this charming Alpine gem in shrubby horders, which more or less are shadowed by trees? The answer is liquid manure given in winter. Mr. Williams must have been reading the *Journal* and testing some of the unorthodox suggestions occasionally found therein, and the experiment has proved a distinct success. The *Anemone* flowers that have covered the border for weeks were twice the size they are usually seen, and their chaste beauty was unmistakable. The roots are never disturbed, and plants spring up in great informal masses, and on that account are perhaps the more enjoyable. It is clear they like liquid manure in the

winter, and the soaking in January benefited everything else in the border, trees and flowers alike.

#### THE ROSMRY—A GOOD MANURE.

Then we come to the Rose garden. It is just a slice of one end of the lawn, and divided from it by a Yew hedge, the boundary wall affording shelter from the opposite side, the greenhouse and wall on the north and a tall hedge with outside screen of trees completing the shelter all round. The space may be about 30 to 40 yards wide and 50 to 60 long, sloping to the south. With the exception of a line of Carnations and Pansies, and a bed of Delphiniums on the north or shaded end, it is all Roses, mostly dwarfs, planted 2 to 3 feet apart on the level, with Teas on raised beds on the west border, and some covering the wall. It is plain to see by the stumps that the growth last year was remarkable. Mr. Williams is a close pruner, but the winter's severity left him no choice, and not a few of his plants or bushes have had to be levelled to the ground. But most of them are pushing up fat deep green shoots. So strong are they that many will probably be topped shortly, and there can be little or no doubt that the second or axillary growths will be quite sufficiently vigorous for supporting fine blooms, while a more compact habit of growth will be secured. Roses on walls have not been injured by the winter, and their vigour is extraordinary. A Belle Lyonaise on the stable, a beautiful Rose, but with many growers "shy," has a bud in apparently every shoot, and there are hundreds of them. Pruning to moderately strong hard wood, not close spurring, is adopted with this fine tree. The ground is deeply trenched and well manured. Rose-growing was tried without trenching, "but it would not do" where first-class blooms were expected. The manure used is rich in potash, phosphates, and nitrogen, dry wood ashes passed through earth closets, and it tells its tale wherever it is applied. If any reader should wish to have something of the same nature prepared in a different way here is a simple formula. Take 1 lb. of dry wood ashes, 2 ozs. of bonemeal, 1 oz. of sulphate of ammonia; mix, apply this quantity to a square yard of Rose bed, and await results. This simple mixture will be found good for other plants, crops, and trees that require more support than the soil contains. The same generous treatment accorded by Mr. Williams in his Rose garden enables him to obtain a great quantity of vegetables from a small plot of ground, and a bed of Bath Cos Lettuce with not a blank in it, except by removals for use, would have gladdened the eyes of many a gardener if he had it at home, for such beds were undeniably few and very far between during the first week in May. We are busy "gardening" till nightfall, take a stroll to the tune of the nightingale's trill, retire, for we have a long day before us on the morrow and must be up with the sun. Mr. Williams has an appointment with a friend some miles distant, and I have the privilege of his company.

#### SHAKESPEARE'S LAND.

Stratford-on-Avon is about five miles from Alderminster, and so curiously do counties dovetail into each other, that we have to cut across the corners of two or three to reach the station. The drive is delightful, the morning bright, and the nightingales still singing in the hedgerows. The field culture is also better; the home farm of Mr. West showing what can be done in developing the resources of the soil. It is far within the bounds of truth to say that if all the land in the Midlands were managed like his the produce would be trebled and more. These bright spots demonstrate that the land is capable of improvement, and without better culture it is futile to expect prosperity. But we are nearing the town in which pilgrims from many lands assemble, and must leave farming for a moment. But stay, was not Shakespeare a farmer? If he was not, how came it that he sued Philip Rogers, in the Borough Court of Stratford, for 35s. 10d. for corn delivered to him at various times? He was that, and much more. He was a man of many talents; yet as Emerson says, "they never seduced him into ostentation, nor did he harp on one string; he has no peculiarity; no discoverable egotism; the great he tells greatly, the small subordinately. He is wise without emphasis or assertion; he is strong as Nature is strong, who lifts the land into mountain slopes without effort, and by the same rule as she floats a bubble in the air, and likes as well to one thing as the other." Such is the estimate of the great man by a great essayist. The beautiful church in the valley contains the bones of the world-famed dramatist, preserved, mayhap, by the memorable invocation and the curse that covers them:—

"Good friend, for Iesus sake forbear,  
To digg the dust enclosed here;  
Blest be ye man yt spares thes stones,  
And cvrst be he yt moves my bones."

Let them rest. His works are imperishable, and his memory appears to be more cherished as years roll round. The fine new Memorial Theatre, to which Mr. Flower has contributed £22,600, and endowed with several tenements, is evidence of this; and the bard's house is prized as a jewel—set, it must be said, in a clean and beautiful town. We did not tarry long, yet just long enough to lose the Worcester train for Stourport, which would be met. What is to be done now? "Oh! I have it; wire Stourport to keep the carriage; go round by Birmingham to Kidderminster, then cut across country, and we shall only keep the coachman a quarter of an hour." The quickly arranged programme was carried out to the letter, and we were next on our way to

#### ABBERLEY HALL.

It was a delightful drive of about seven miles, through a generally well, and in places admirably cultivated, district; orchards near and distant, like masses of silvery clouds, for the Plums and the Cherries were

laden with blossom. This may perhaps be called the Dandelion wine district, for children appeared to be determined to gather all the flowers of that plant, which they sell for 1d. a quart for wine-making in the town. Steadily rising, the rendezvous was eventually reached, nearly 700 feet above sea level; and what a view! Abberley Hall is a noble mansion. On the one side we look down on Witley Court with its golden dome; on the other we see in the distance the mountains of Wales; in the immediate foreground, on the south, is the lofty eminence, Abberley Hill, from which eleven counties are brought within the range of vision; on the north the eye rests on the clock tower, which, taking it all in all, can scarcely have an equal in this country. It is a new, great, and substantial work, and could only be completed at enormous cost. The architect, Mr. St. Aubyn, has produced a monument of art. The clock is illuminated at night, and the chimes, which consist of twenty bells, ranging in weight from nearly 4 tons downwards, fill the air with music every three hours, playing some forty or fifty tunes in turn, full, rich, and melodious. The tune selected for the day, in celebration of some nuptials, was "Haste to the Wedding," and nowhere else could it be similarly rendered. The owner of Abberley, J. J. Jones, Esq., has, moreover, a private band, which discourses in the elegant stand on the lawn during dinner on summer evenings, and on the great monthly luncheon days, when guests assemble from all around. Abberley is one of those country seats where wealth and a spirit of improvement are evidently co-existent. There is no resisting that overpowering impression. It is apparent in everything and everywhere. A wilderness is being transformed into a pleasure ground, and rookeries and rockeries formed in suitable positions; and as water is scarce, a "tank" is being made about 1½ acre in extent, and as it is on a hillside it is a stupendous work, will, in fact, when completed, be a miniature lake with its island and fountain—a great ornament, and of greater value, for pipes will be laid from it for conveying water to the lower grounds and gardens. Of these a rapid glance could only be had. There are good ranges of glass, good Vines, and provision appears to be made for a bountiful supply of hardy fruit. Noticeable was an Eucalyptus tree that had passed the winter with surprising little injury. The high bank on which it stands, and the great altitude, have doubtless contributed to its hardiness. It is pleasing to observe further that the proprietor of Abberley does not live for himself alone. The tenants' dining room, with the different phases of agriculture painted on its walls, affords ample proof of this, for it serves also for a theatre, concert room, or lecture hall for the estate community. Abberley was a great surprise, and the few hours all too short for inspecting its many features of interest, which are such as to create a longing to see them once again.

The homeward journey was *via* Worcester to Oxford, through Evesham and Pershore, famed for fruit culture, and the Plum and Cherry orchards were in the zenith of their spring beauty. A few hours afterwards the "Lights of London" were in view, and the "day into the country" was brought to a close.—A CITY MAN.

#### THE ORCHID SHOW AT BIRMINGHAM.

MAY 12TH AND 13TH.

A BRIEF outline of this Exhibition was given in our last issue, but it well deserves a fuller description than the short time at our disposal allowed us to furnish then. It was a remarkable Show, in every respect highly creditable to those who contributed to its attractions, and to the Curator and Committee of the Society who so ably carried the idea into execution. Most unfortunately, however, the weather was extremely adverse, rain falling heavily on both days; and though the Exhibition must be characterised as a decided success horticulturally, it is feared that there will be some financial loss, as the prize fund was a heavy one and the greater portion was allotted to exhibitors. With such strong local support it may be expected that the experiment will be repeated another year, and should this be the case we hope the weather conditions may prove more favourable, so that a substantial balance may be obtained.

The value of the prizes was noted last week, and some additional notes on the classes may now be given. Four classes were appropriated to nurserymen, but Mr. J. Cypher was the only exhibitor in each, taking the premier prizes in those and two open classes. Very seldom indeed has he scored such profitable victories. The Cheltenham plants throughout were healthy well-flowered specimens, of moderate size, and affording good evidence of the careful treatment they receive. The premier collection of twenty Orchids constituted a beautiful group, comprising the following plants:—*Cattleya Skinneri oculata*, a beautiful variety, of high colour, with a light throat to the lip; it had six racemes of about five flowers each. *Dendrobium thyrsiflorum*, a grand plant, in fine condition, bearing forty handsome spikes; *Cypripedium Lawrenceanum*, a beautiful plant, with two dozen flowers; *Oncidium concolor*, very bright yellow, seven racemes; *Odontoglossum Roezli*, a vigorous plant, with nine racemes; *Cattleya Mossiae grandiflora*, well flowered; *Anguloa Clowesi*, four large flowers; *Laelia elegans*, the same number; *Dendrobium nobile*, in capital condition, bearing some scores of flowers; *Odontoglossum citrosimum*, three racemes; *Cypripedium biflorum*, a pretty variety, with twenty-eight flowers; *Dendrobium crystallinum*, loaded with flowers; *Cattleya Mossiae*, a strong handsome plant, twenty flowers; *Calanthe veratrifolia*, four racemes of its pure white flowers; *Cypripedium villosum*, a strong specimen, with twenty large flowers, a particularly good variety, the flowers suffused with a bright yellowish tint; *Cattleya Mendeli*, with a dozen flowers of a good variety; *Vanda suavis*, well grown, three racemes of nine and ten flowers each; *Laelia purpurata*, fifteen flowers; *Saccolabium*, two racemes; and *Dendrobium chrysotoxum*, twelve drooping racemes of bright yellow. The second place in this class was worthily gained by A. Wills, Esq. (gardener, Mr. J. Morgan), whose plants were smaller than those from Cheltenham, but they were all in admirable health, and the group contained several species or varieties of sterling merit. Especially notable was a grand *Dendrobium*

Falconeri on a block, and representing one of the best varieties we have seen. The flowers were over 4 inches in diameter, with a fine expanded lip, which with the sepals and petals was deeply tipped with an intensely rich crimson. Other remarkable plants were the beautiful but rather troublesome *Lælia majalis*, with three large flowers, the pure white *Dendrobium Dearei*, *Masdevallia amabilis*, a good variety of *Odontoglossum nebulosum*, *Dendrobium chrysanthum*, and *Epidendrum vitellinum majus* exceedingly bright.

The second class in the schedule was for ten Orchids from amateur growers, and the prizes in this were the most keenly contested of all, four good collections being entered. The well-known Birmingham amateur, C. Winn, Esq. (gardener, Mr. G. Barnes), secured the premier honours for most creditable plants, the strong growth, fresh green foliage, and bright clean flowers of which afforded the best testimony of the treatment they received being well adapted to their requirements. The plants shown were as follows—*Cypripedium barbatum*, three dozen flowers; *Masdevallia Harryana*, twenty brightly coloured large flowers; *Odontoglossum Roezli*, fifteen flowers; *Oncidium Marshallianum*, very bright; *Cattleya Mendeli*, eight flowers; *Odontoglossum Alexandræ*; *O. vexillarium*, one of the plants that are especially happy in Mr. Winn's collection, the specimen staged having racemes of six or more flowers each, of fine size, form, and colour; *Cypripedium Lawrenceanum*, *Lælia purpurata*, and *Cattleya Mossiæ* being other notable plants. Following very closely in this class was the Right Hon. J. Chamberlain, M.P. (gardener, Mr. E. Cooper), whose plants were healthy, well flowered, and fine varieties; *Oncidium Marshallianum*, *O. concolor*, with six large racemes; *Cattleya Mossiæ*, *Dendrobium thyrsoflorum*, and *Cattleya citrina*, with eleven large yellow fragrant flowers were the leading specimens; *Odontoglossum Halli leucoglossum*, with large flowers, a very pretty variety, also being notable. The third place was accorded to Joshua Fellows, Esq., his examples of *Lælia purpurata*, *Ada aurantiaca*, *Phalænopsis Luddemanniana*, and the wax-like *Chysis bracteosa* were scarcely equalled in the Show. An extra prize was deservedly awarded to E. Wright, Esq. (gardener, Mr. Hodges), for well-grown plants of useful varieties. A class for ten Orchids was also allotted to nurserymen, but Mr. Cypher was the only exhibitor, and won the premier prize for plants of similar merit to those he had in the open class. They were as follows—*Dendrobium crystallinum*, seven racemes; *Lælia purpurata*, eight large flowers; *Dendrobium Bensoniæ*, most profusely flowered; *Calanthe veratrifolia*, *Cattleya Mossiæ*, *Oncidium sphacelatum*, *Cattleya Mendeli*, ten flowers; *Vanda suavis*, *Cattleya Skinneri*, a handsome specimen with six racemes of twenty-three richly tinted flowers; and *Dendrobium thyrsoflorum* with six long racemes, very beautiful.

Two classes were devoted to groups of six Orchids, the premier position amongst the amateurs being gained by the Right Hon. J. Chamberlain for capital specimens of the following—*Dendrobium densiflorum*, forty racemes of flowers; *Lælia purpurata*, seven racemes, three to five flowers each; *Cattleya Mossiæ*, nine flowers; *Lælia elegans*, good variety; *Odontoglossum Alexandræ*, large flower; *Aerides Lobbi*, three long racemes, and *Oncidium Marshallianum* with three spreading panicles of brilliant yellow flowers. Mr. C. Winn and Mr. E. Wright were placed second and third, both showing fresh and well-grown plants. Mr. J. Cypher had the nurserymen's class to himself, and again secured the first prize.

The *Odontoglossums* were not so numerously shown as might have been expected considering the large number grown. The best amateur's collection of ten distinct *Odontoglossums* were contributed by Mr. C. Winn, the plants of medium size, but well flowered, and including fine varieties of *cirrhosum*, *triumphans*, *citrosium*, *Alexandræ*, *Cervantesi*, *prænitens*, *luteo-purpureum*, *vexillarium*, *tripudians*, and *Roezli album*. Mr. J. Fellows was awarded the second prize for some well-grown plants in pans and baskets, admirably flowered, and of excellent varieties. The best were *citrosium*, *vexillarium album*, *Oerstedi*, *Rossi majus*, *Cervantesi*, and *Alexandræ*. Mr. Cypher's plants, which were first in the nurserymen's class, were larger and finely flowered, representing *Roezli* and *Roezli album*, the latter with fifteen flowers, *triumphans*, very richly coloured, *vexillarium*, *Alexandræ*, *Rossi*, dark coloured, *citrosium*, *Halli*, *Pescatorei*, and *Cervantesi*.

*Cattleyas* and *Lælias* were provided for in two classes like the preceding. Mr. C. Winn secured first honours in the amateurs' class with half a dozen medium-sized but healthy and profusely flowered plants of *L. purpurata*, eight large flowers, *L. cinnabarina* and *L. elegans*, *C. Mendeli*, *C. Mossiæ* in first-rate condition, and the new *C. Lawrenceana*, which is fast becoming a favourite. Mr. Chamberlain's second prize collection comprised larger and more showy plants, but they were not so distinct as the first, there being two varieties each of *C. Mossiæ* and *Mendeli*, *L. elegans alba* also being a noteworthy plant. Mr. Cypher followed up his good fortune by gaining another first prize, without any competition, in the class for six *Cattleyas* or *Lælias*, the best of all being a charming example of *C. citrina* on a raft, the plant bearing nine handsome flowers. *D. Mendeli* and *Mossiæ* were both good, as were the varieties of *L. purpurata*, *alba* and *prasiata*.

*Masdevallias* were shown by two exhibitors, and the difference was similar to that in the amateurs' class for *Cattleyas*—namely, one had a collection of well-grown and profusely flowered plants, but less distinct, and the other had smaller plants of less effective species but all distinct. As the prizes were offered for "twelve distinct species," the last-named complied more nearly with the terms of the schedule, but this consideration was overruled in regard to the superior attractions of the others, and Mr. C. Winn was placed first with some beautiful varieties of *M. Harryana* and *M. Lindeni*, some bearing twenty flowers or more, with *M. Veitchi* and a few others. Mr. J. Fellows, who was second, had good examples of *Harryana*, *triangularis*, *Estradæ*, *Schlimi*, *ludibunda*, *Houttæana*, *Veitchi*, *Lindeni*, *igneasplendens*, and *amabilis lineata*.

The prizes for twelve cut spikes or bunches of Orchid flowers were awarded to Mr. J. Cypher, Mr. C. Winn, and Mr. J. Chamberlain in the order named, the species represented in the first-named collection, which were tastefully arranged in ornamental glasses, being as follows—*Cattleyas Skinneri*, *Mossiæ*, *intermedia*, *citrina* and *Triangæ*, *Dendrobiums formosum*, and *nobile*, *Odontoglossum Pescatorei*, *Oncidium ampliatum*, *Vanda suavis*, and *Cypripedium Dominyanum*. Mr. Winn's flowers were chiefly *Cattleyas*, *Dendrobiums*, *Cypripediums*, *Odontoglossums*, and *Masdevallias*, Mr. Chamberlain having *Cattleya citrina* and *Thunia Marshalli* very fine.

The non-competing exhibits comprised several groups of Orchids and

other plants, for which extra prizes and certificates of merit were awarded. Mr. C. Winn had a choice group of Orchids tastefully arranged and representing a number of species. Mr. Hugh Nettlefold, Hall Field, Edgbaston, also contributed a group of Orchids, a specimen of *Dendrobium nobile* being very large, and the variety an excellent one. Mr. J. Chamberlain exhibited a small collection of choice Orchids, amongst which the distinct and curiously coloured *Epidendrum Wallisi* was very notable. J. E. Wilson, Esq. (gardener, Mr. T. Jenks) had a magnificent example of *Dendrobium nobile*, over 4 feet in diameter and loaded with flowers, amply meriting the prize awarded for it. Mr. Hans Niemand, Harborne Road, Edgbaston, showed a light and graceful group of plants admirably arranged by Mr. Spinks, Lilies, Roses, Richardias, and Azaleas forming the foundation of the group, with a groundwork of Ferns and *Isolepis* and bands of the Hoop Petticoat Narciss. Mr. R. H. Vertigans showed a collection of Alpine plants in many varieties, including some neat and pretty varieties.

First-class certificates were awarded for the following:—*Dendrobium Wardianum Wrighti* (E. Wright, Esq.).—A variety with exceedingly large flowers, the sepals and petals broad, the lip deeply tinged with crimson.

*Gymnogramma Lathamæ* (Mr. W. B. Latham).—An extremely handsome graceful Fern, with long broad fronds very finely divided into linear segments like some of the dimorphous *Aspleniums*. It is of strong habit and one of the most ornamental forms of the genus. It is said to be of hybrid origin, and originated in the Birmingham Botanic Garden since this has been under Mr. Latham's charge.

## MIGNONETTE IN POTS.

(Continued from page 377.)

It is not always convenient to affix the trellises to plants before branches extend, pressure of other work and want of space prevents this being done. At this stage two persons are then required instead of one to do the work, and the shoots are often broken in the operation. To remedy this the central wirework should be dispensed with, and the trellis composed of two circular hoops, instead of four or five, as is usual. When this is done the continuations of the stem must be longer, so that they will reach the outer circle, which leaves the centre entirely open. The plants, even if they have branched freely, can be placed on this trellis without any fear of breaking the shoots, and by one person in less time than two could manage the others.

When the plants are once placed on the trellis, the flowers as they appear should be removed, and the shoots tied down to bring them to the base as early as possible. If a good branching strain is grown they will branch freely enough by the removal of the flowers without having to pinch the shoots. Another matter of some importance at this stage, when a regular head of bloom is required, is to stop the whole of the shoots, not only those that are showing flower, but those that are not so, that the whole will break again and come into flower together. When trained bush-shape, considerable care is necessary in order to have well furnished specimens. The shoots from time to time must be pinched until the whole plant has been well furnished with growing shoots. They may then be allowed to extend and produce their flowers. Before these open, however, some shoots will need re-tying, for they are certain to take the lead of others, and if this is attended to there is no difficulty in having a bush well furnished with spikes from the base to the top.

From the time the plants are established in their largest pots and have been furnished with their trellises they may be grown in deep frames. They appear to do better in such positions with their heads close to the glass than in the greenhouse. They will do very well in the latter structure if they have plenty of light from above, but in whatever position they are grown the pots should stand on ashes or some similar moisture-holding material. If the pots stand upon a dry base the plants do not make satisfactory progress. They are better in frames, because the pots in a large measure can be shielded from drying influences, and evaporation is not so great. Air should be freely admitted on all favourable occasions after the plants are once growing freely, for these plants cannot endure a close confined atmosphere in any stage of growth. Without abundance of air they grow weakly, and no after treatment will enable them to produce large fine spikes. The object to be attained is a strong sturdy growth in all stages of development. When drying winds prevail it is very much better to keep the frame comparatively close and apply a light shade than expose the plants to its withering influence.

By the end of September the earliest plants will have furnished their trellises, and should be removed from the frame to a light cool position in the greenhouse. The plants should be arranged close to the glass, and where a circulation of air can be freely admitted to them. Even during the winter the pots should not stand upon a dry base, and the plants must be kept cool, using as little fire heat as possible. They will do very well in a night temperature of about 40°, on mild occasions 5° more will do no harm, but if sharp the temperature had much better be 2° lower than above. With this treatment the plants will remain in good condition, and the growth they make will be sturdy and strong. From the first batch a succession of flowering plants can be maintained from November until the end of May, or even longer. They are readily retarded by the removal of the flowers. Even those that flower first after they fade and are removed, or cut for use in vases, soon break again into growth, and in due time flower profusely.

During bright sunshine light shade should be provided, yet care must be taken that light is not excluded by the material used. Every ray possible must be admitted them. The growths of the plants are certain to flag if exposed to the full force of the sun during summer, and also during the months of April and May, when the plants are flowering under glass.

One of the main points in the successful cultivation of Mignonette in pots is watering. If carelessly watered failure is certain, and if particular attention in this respect cannot be given the culture of these plants had better not be attempted. The soil in which they are growing should never become dry from the time the seed is sown until the plants are ready for throwing away. If once dry during the growing season the growths become woody and fail to extend, but make small short-jointed shoots that are continually producing small flowers. If dry during the winter the foliage turns brown and disfigures the plants, besides considerably dwarfing the flower spikes. If, on the other hand, the soil is constantly wet by over-watering, they are certain to go off. In either case the fine thread-like roots of these plants quickly perish. When the plants are watered a good soaking should be given, and should then remain until the soil is nearly dry before more is applied. The plants are much benefited by being syringed twice daily during the summer, or whenever the weather is favourable and will allow of this being done. At the same time the walls and vacant portions of the frame should also be well moistened. No feeding will be needed until the plants have filled their trellis. An occasional application of clear soot water is very beneficial; it acts quickly upon the plants, and imparts to the foliage a fine dark colour. The most reliable system of feeding is to apply artificial manure to the surface of the soil. About half a teaspoonful is sufficient for 10-inch pots, and this may safely be applied about every third week. It is surprising how quickly they come up to the surface and take possession of it. When we fed the plants with liquid manure there was always an absence of active roots on the surface; in fact the roots appeared to be driven downwards, which led to this practice being discarded. The surface soil is full of roots and perfectly sweet by the system of feeding with top-dressings.

For cutting in autumn, say from the time the supply outside fails until near Christmas, it is a good plan to prepare a patch of ground by the addition of manure and a little fresh loam, and sow it with seed about the middle of June. The common garden variety will do very well for this purpose. The seedlings, when large enough, should be thinned out, leaving them 3 or 4 inches apart, so that they will have room to develop without being crowded. This bed should be covered with a frame towards the end of September, so as to protect the plants from frost and heavy rains. In most seasons the supply fails outside by the end of October, and cutting can then commence from this frame, which will yield a supply for a long time if protected from sharp frosts by covering the frame with mats. A frame should be sown towards the end of February or early in March, which will yield a supply fully a month before it can be cut from the open borders. This will be found invaluable, and clear the houses and frames of pot plants much sooner than would otherwise be the case. —N. G.

### BATH SPRING SHOW.

MAY 12TH.

As far as the extent and quality of the exhibits were concerned this may be said to be an unqualified success, but unfortunately most unfavourable weather was experienced, and a heavy deficit was the result. Rain was badly wanted, but a heavy and steady downfall, such as fell throughout the Show day, is bound to keep away all but the most enthusiastic of flower-loving visitors, and it was after all poor consolation to the Committee to know that "their loss was the country's gain."

**AZALEAS.**—There were fewer of these than usual, a difficulty having been experienced in keeping them late enough. W. Long, gardener to C. Gardiner, Esq., was awarded the first prize for twelve grand pyramids, which with two exceptions were at their best. Very fine were the specimens of Magnet, Souvenir de Prince Albert, Duc de Nassau, Roi d'Holland, Stella, Iveryana, and Criterion. Mr. W. C. Drummond took the third prize for an uneven and poor collection. The first prize for nine specimens was easily won by Mr. J. Cypher, Cheltenham, who had globularly trained freely flowered examples of Model, Criterion, Nulli, Reine de Pays Bas, and other popular sorts. Mr. H. Keel, gardener to Colonel Landon, also exhibited in this class, but only secured a third prize. Mr. J. F. Mould, Pewsey, was first with six varieties, these including Incomparable and Sankai in good condition; and Mr. A. Hawkins, gardener to T. Jolly, Esq., was third.

**STOVE AND GREENHOUSE PLANTS.**—The twelve flowering plants that gained Mr. Cypher the premier prize were exceptionally fine, and most probably some of the specimens are superior to any of the kind hitherto staged. They consisted of *Dracophyllum gracile*, *Pimelea Hendersonii*, a fine globular plant about 5 feet across and loaded with bloom, *Franciscea eximia*, *Azalea Magnifica* grandly flowered and fully 6 feet through, *Anthurium Schertzerianum densifolium* with thirty-two fine spathes, *Erica affinis*, *E. Cavendishii* richly coloured, *Aphelaxis macrantha purpurea*, *Hedera tulipifera*, *Azalea Cedo Nulli*, *Anthurium Schortzerianum*, a fine form with thirty-six spathes, and *Pimelea spectabile*, a magnificent plant from 5 feet to 6 feet through. Mr. W. Long was placed second with a creditable collection, though not so good as he exhibited last May. With nine plants Mr. J. F. Mould was a good first, having among others medium-sized well-flowered specimens of *Erica ventricosa coccinea*, *E. affinis*, *E. Victoria Regina*, *Hedera tulipifera*, and an *Anthurium*. Mr. G. Tucker, gardener to Major W. P. Clarke, Trowbridge, was a good second, his best being *Anthurium Schertzerianum*, *Erica alba*, and *Clerodendron Balfourianum*. Mr. W. J. Mould, gardener to E. E. Bryant, Esq., was third. The prizewinners with six varieties were Messrs. W. C. Drummond and A. Hawkins. The first prize for a single specimen was awarded to Mr. Cypher for *Anthurium Schertzerianum* Cypheri, this, the largest of all the forms, having thirteen grand spathes. *Ericas* were well shown by several growers, though the majority had half specimens only. Mr. Cypher was first for four varieties, these consisting of *E. ventricosa magnifica*, *E. ventricosa coccinea major*, *E. depressa*, and *E. Cavendishiana*, all of good size and

well flowered. Mr. W. J. Mould was second, and Mr. J. F. Mould third. Mr. Cypher was also first for a single specimen, and Mr. Long second. Five-foilage plants were not so good as usual. Mr. Cypher was first for fifteen varieties, these including *Kentia Fosteriana*, *Pritchardia pacifica*, *Kentia australis*, *Latania borbonica*, and *Thrinax elegans* in good condition. Mr. W. Long was a fairly good second. Mr. W. C. Drummond was first for nine varieties. Several good groups of Ferns were shown, those from Trowbridge being the most attractive. Mr. G. Tucker had the best fifteen varieties, these including *Gymnogramma sulphureum*, *Asplenium nidus avis*, *Adiantum cuneatum*, *Cheilanthes*, *Lomaria giganteum*, *Cheilanthes hirta*, and the handsome and seldom-seen *Athyrium Goringianum tricolor* in good condition. Mr. W. J. Mould was a good second, and Mr. J. Coke, gardener to A. P. Stancombe, Esq., third. Mr. W. C. Drummond had the best nine varieties, and Mr. W. Marchant, gardener to Jerome Murch, Esq., was second. Roses in pots were scarcely so fresh as usual, but several of the exhibits were very creditable. Mr. W. Taylor, gardener to S. P. Budd, Esq., was deservedly first for nine varieties, of which the best were Catherine Mermet, Pauline Labonte, Celine Forestier, Edouard Morren, La France, and Dupuy Jamain. Mr. J. E. Morris, gardener to R. B. Cater, Esq., was a good second, his best being *Maréchal Niel*, *Rubens*, *Madame Clemence Joigneaux*, and *Charles Lawson*. For six varieties Mr. A. Hawkins was first, the second prize going to Mr. A. W. Southard, gardener to F. J. Walker, Esq. Mr. Cypher was easily first for nine large-flowering *Pelargoniums*, these consisting of C. Outram, Miss Simpson, Decorator, Digby Grand, E. Perkins, *Triomphe de St. Mandé*, *Rob Roy*, and *Lady Isabel*, all fresh and good. Mr. G. Tucker also had several good plants, and took second prize. The best six varieties were staged by Mr. A. J. C. Bess, Bath; and Mr. J. Mattock, Oxford, was a close second. The prizewinners with *Calceolarias* were Messrs. Tucker, W. Robinson (gardener to Lord Justice Lopes), and W. Marchant; and with *Cinerarias* Messrs. J. E. Morris, W. Marchant, and J. Southard, the exhibits being meritorious in each instance.

**ORCHIDS.**—These would appear to be gaining in popularity with the citizens of Bath, and several new growers are commencing to exhibit them, one of the latter, the Rev. E. Handley, taking the first prize for six varieties. These consisted of *Dendrobium thysiflorum*, *Cattleya Mossiae*, *Oncidium Marshallianum*, *Cattleya Mendelli*, *Laelia purpurata*, and *Odontoglossum Roezlii*. This exhibit, as well as others that won prizes, was somewhat marred owing to the pots being "made up" without due regard to the variability of the varieties, two or more forms being included in one make-up specimen. This ought to be avoided in the future. The second prize for six varieties went to Mr. F. Perry, gardener to H. Cruger Miles, Esq., Bristol, who had good examples of *Cattleya Mossiae*, *Oncidium macranthum*, and *Masdevallia Lindenii*. Mr. J. Cypher was third. With four varieties Mr. F. Perry was a good first, his best being *Cymbidium Lowianum*, *Laelia cinnabarina*, and *Masdevallia Lindenii*. Mr. W. J. Mould followed, showing *Aerides Fieldingii* and *Dendrobium thysiflorum* in good condition; and Mr. J. E. Morris was third, noteworthy among his being *Cattleya Mossiae* and *C. speciosissima*. The latter was first in the amateurs' class for a single specimen, having *Cattleya Mossiae* with ten fine blooms; and in the open class the Rev. E. Handley (gardener, Mr. J. Frost) was first with *Odontoglossum citrosum*.

**CUT FLOWERS.**—Cut Roses are invariably good at the Bath Shows, and on this occasion several growers had stands of very fine blooms. Mr. J. Mattock, Oxford, was placed first for twenty-four good blooms in twelve varieties, *Niphetos*, *Perle des Jardins*, *Anna Olivier*, *Souvenir d'un Ami*, *Madame Willermoz*, *Hippolyte Jamain*, *Auguste Rigotard*, *Madame Welch*, and *Jean Pernet* being the best. The second prize was awarded to Mr. W. Taylor, who had Catherine Mermet, *Niphetos*, *Countess of Oxford*, *Madame de Watteville*, and *General Appert* in good condition. Messrs. G. Cooling and Son obtained the remaining prize with a creditable stand somewhat lacking variety, but which included very fine blooms of *Maréchal Niel*, *Paul Neron*, *Countess of Oxford*, *La France*, and *Dupuy Jamain*. With six varieties Mr. E. S. Cole, gardener to W. Pethick, Esq., was first; Mr. J. Curtis, gardener to W. W. Kettlewell, Esq., second; and Mr. W. C. Drummond third. A grand stand of *Maréchal Niel* was shown, not for competition, by Messrs. G. Cooling & Son; Mr. Mattock also brought an extra stand of good Roses; and Mr. T. Hooper, Bath, staged a box of *Maréchal Niel*. The competition with twenty-four varieties of cut flowers was close and good, a considerable number of Orchids being included. Mr. F. Perry was first; Mr. E. Miller, gardener to F. Tagart, Esq., Bristol, second; and Mr. W. J. Mould third. With twenty-four Pansies Mr. T. Hooper was first, and Mr. W. Meddick second; and with twelve varieties Messrs. H. Hooper, G. Hooper, and W. Meddick were the prizewinners. Bouquets were of great excellence, the prizewinners (Messrs. W. Dobson, C. Winstone, and E. S. Cole) all coming from Bristol. Vases of flowers were also as near perfection as possible, the prizewinners being Messrs. W. Dobson, H. Mardon, and E. S. Cole. Mr. J. R. Pearson, The Chilwell Nurseries, Nottingham, exhibited three stands of cut blooms of Zonal *Pelargoniums*, for which Messrs. Pearson have long been noted, and these attracted much attention. A considerable number of the varieties were unnamed seedlings, these being certainly superior to the older sorts. Such named varieties as *Lady Chesterfield*, *Lord Chesterfield*, *Cato*, *Alex. Albrecht*, *Mrs. Gordon*, *Miss Hamilton*, *Aspasia*, *Zelia*, *Octavia*, and *Mrs. H. F. Barker* were among the best represented.

**FRUIT AND VEGETABLES.**—Strawberries were not so plentiful as usual. For six plants in pots Mr. J. Weston, gardener to Rev. C. C. Layard, was first, having *Oscar* in good condition. Mr. G. Pymm, gardener to Mrs. Goldsmith, Trowbridge, was first for a single dish of Strawberries, staging *J. Veitch* large and bright in colour. Mr. Robinson was second, and Mr. J. G. Kitching third, both having large but rather rough fruit of *President*. Messrs. F. J. Walker and E. T. Hill had the best Apples, and Messrs. F. Evry, E. T. Hill, and A. T. Hall were successful with Pears. There were nine classes for vegetables, all well filled. The most successful exhibitors were Messrs. Pymm, A. Beavis, J. Long, T. Evry, G. Garraway, W. G. Tylee, J. Weston, G. Horsell, F. Evry, and J. Ashton. Classes were also provided for cottagers, and it was a surprise to some to find that these could also exhibit early Potatoes, Asparagus, Seakale, and other choice vegetables.

## ORCHIDS AT UPPER HOLLOWAY.

VISITORS to the Victoria and Paradise Nurseries, Upper Holloway, at this time of year have become accustomed to the beautiful displays of Orchids there provided by Mr. B. S. Williams, but this season he has far surpassed his previous efforts both in the variety and tasteful arrangement of the exhibition. The house devoted to the Orchids is the spacious structure near the office, 100 feet by 22 feet wide, and with a wide path from end to end, allowing visitors to inspect the floral attractions without any inconvenient crowding. The stage on the left hand side when entering has a particularly fine appearance, an appropriate background of Palms and Ferns being formed, the glass being covered to the eaves of the house with green calico, which enables the colours of the flowers to be seen to much better advantage. The Orchids are not arranged formally but freely at different levels, with the racemes or panicles of flowers arching over the others, and with graceful Ferns, Selaginellas, and other fine-foliage plants intermixed. Upon the right hand side larger Palms and Tree Ferns are arranged with Orchids in part, and in a prominent position is a tree stem with branches, upon which are disposed numerous epiphytal Orchids suitable for growing in this way, and very pretty are the numerous plants of *Cattleya citrina*, *Dendrobium* (or *anousmum*), *Odontoglossum Alexandræ*, *Oncidium concolor*, *Epidendrum vitellinum majus*, *Trichopilia coccinea* and *Burlingtonia fragrans*, with a few *Tillandsias* and other Bromeliaceous plants.

In the general effect *Lælia purpurata* takes an important part, the flowers large and some of the varieties very handsome. There are over twenty fine specimens, all flowering freely, and in the other houses there are some scores advancing to maintain the display. One variety named *bella* is distinguished by its purple sepals and petals and intensely rich crimson lip; in contrast with this *L. purpurata alba*, with pure white sepals and petals, has a charming appearance. *Cattleyas*, comprising the floriferous *C. Lawrenciana*, the exquisitely delicate *C. Morganæ*, which was admirably figured in the "Orchid Album" a short time ago, *C. Mendeli*, and *C. Mossiæ*, in many fine varieties, some with twenty or more flowers, add considerably to the beauty of the exhibition. *Odontoglossums* are also numerous, and the varieties of *O. crispum* are remarkable throughout for their high quality, grandly proportioned substantial flowers, pure white, tinted or spotted, the result of many years' careful selections from extensive importations. *O. Pescatorei*, *O. luteo-purpureum*, *O. cirrhosum*, *O. vexillarium* and *O. gloriosum*, *O. citrosum* and its lovely variety *roseum*, suspended in pots from the roof, are extremely beautiful, the drooping spikes showing to good effect in this way. Of *Oncidiums* there are many of the best species, but particularly fine is the brilliant golden *Marshallianum*, which is now in its best condition; *O. concolor* is also abundant. *Epidendrum vitellinum majus* furnishes some bright scarlet tints; *Dendrobiums*, such as *thyrsoflorum*, *Wardianum*, *draconis*, and others add to the general attractions; *Cypripediums* of many species, varieties, and hybrids, *Vandas* (about twenty plants of *tricolor*, *suavis*, &c.), *Miltonias*, *Lycastes*, *Trichopilias*, and innumerable others are represented by hundreds of plants, and it can readily be imagined that a very beautiful display is produced. The show will attract many visitors during the next few weeks, and there are plenty of plants in reserve to maintain or even increase its interest.

In the other portions of the nursery choice Ferns, Pitcher Plants, *Ericas*, and miscellaneous stove and greenhouse plants, of which the collection is so large, all include much that is worthy of inspection.

## SPRING-ROOTED HYDRANGEAS.

THE method adopted by a great many gardeners of striking cuttings of these very useful and beautiful flowers in the autumn is often attended by disappointment. I have seen a quantity of cuttings inserted in pots at that period, and but a few of them have made roots freely and grown into plants suitable for bearing a good truss or two of blooms the following year. Besides, the room occupied by the young plants during the winter months may be utilised for other purposes. When it is necessary to increase the stock or to obtain young ones, cut back the shoots of the old plants, leaving two or three eyes only of the present year's growth; as soon as the wood is thoroughly ripened place them in a cool frame or greenhouse till January or February, and then shift a few of each variety into a temperature of 55° or 60°. They will soon begin to push out sturdy young growths, which, when 2 or 3 inches long, may be cut off close to the old wood, and so secure a heel to each cutting. Put them singly into small pots and plunge in a gentle bottom heat, or they may be inserted in cocoa-nut fibre in a propagating frame and kept air-tight till rooted, which will take place in about three weeks. They may then be carefully lifted and placed in 3-inch pots. Use for this potting two parts of good fibry loam, one of leaf mould, and one of sand. After potting, place the plants in a house or pit where the temperature can be maintained during the day at 60° to 65°, and 55° to 60° at night. Avoid cold draughts. When the roots have taken hold of the new soil and the plants have made two more growths, shift them into a cooler house. If one head of bloom is only required on each plant, keep them in the 3-inch pots till the bloom begins to form, and then repot or feed them with weak liquid manure and a little soot water, which will give

a healthy appearance to the foliage. But if larger plants are required, transfer into 6 or 7-inch pots, using the same compost as advised, only add three parts loam with a little decayed manure and a 6-inch potful of soot to every barrowful of soil. I saw a quantity rooted in this way early in the spring, and they soon outgrew the autumn-struck plants and looked much healthier. Amateurs who have not much room to spare, and florists who want plants in bloom for market in as short a time as possible, will do well to try this method of raising a stock from cuttings. —G. G., *Hunts*.

## PINCHES' ACME TREE LABEL.

I BEG to submit to your notice a new permanent "Acme" label for trees, shrubs, &c., for which I claim some advantages.

1st. The letters are composed of a non-oxidisable alloy, amalgamated with the surface of hard-rolled zinc.

2nd. The names stand out clearly, the letters being nearly half inch high, light on a black ground.

3rd. There is no raised border, so the water runs off freely.

4th. It is half the weight of any other metal label I have seen, without any diminution of strength.

I hope your critical examination of this new label may be favourable.

—JOHN PINCHES.

[It is undoubtedly a good label, light, strong, durable, and the name

Fig. 74.—Acme Tree Label.

clear and distinct. The stem is a foot long, the lower half galvanised, and an inch wide, the plate on which the name appears in raised letters, 5 inches by 2½ inches. It is very suitable for arboretums, pleasure grounds and fruit gardens, in which the names of the trees are desired to be seen without searching among the leafage, or stooping low to read them.]

## STEPHANOTIS.

I HEREWITH send you a shoot in flower of the old variety, if there is more than one variety of *Stephanotis floribunda*. The plant is over twenty years old, and at present is full of flowers, a number of which have a dozen trusses on each shoot. I daresay there are over a thousand trusses upon the plant. It is planted out in the end of an intermediate stove, and is trained along the roof. It has borne a profusion of flowers every year, but this year it has done better than usual.—R. M.

[As to "varieties" of this favourite climber, we have not seen a better than the specimen referred to, nor a better example of culture. The 6 feet long shoot forms quite a wreath of large trusses of fine flowers relieved by deep green glossy leaves.]

## HABROTHAMNUS FASCICULATUS.

THIS *Habrothamnus* ranks, in my opinion, among the most useful of greenhouse climbers. In a dark corner of a cool greenhouse, where few plants would show to any advantage, this vigorous plant can be grown successfully. It flourishes best on a north aspect and in a low temperature, and its clusters of crimson blossoms against a background of dark green leaves make it a decided acquisition. I have seen a specimen on the back wall of a lean-to greenhouse and vinery which had a stair-like stage rising to within a few feet of the glass immediately in front of it, the unsightly back of the stage completely shrouding it. Side by side with it, and likewise nailed to the wall, were plants of *Abutilon vexillarium igneum* and *Tacsonia Van Volxemi*, both in poor condition; while the *Habrothamnus* was in perfect health and a model of what a greenhouse climber should be, with foliage almost to the ground, and one mass of clustering crimson blossoms. The lower clusters were inferior to those at the top, but the effect was very striking. The treatment is very simple. Cuttings from the young shoots may be inserted during the

present month in a compost of loam, peat, and sand, and placed in a warm greenhouse until they are rooted sufficiently to be potted. They succeed best trained or nailed to a wall, or against a pillar in a cool greenhouse, and on a north aspect as before mentioned. The best soil that can be used is two-thirds loam, one-third peat, and sand sufficient to show. It flowers on the current year's wood, and as soon as the flowers fade should be pruned hard—assuming, of course, that the plant has made vigorous growth and covered the space intended for it. Frequent syringings are necessary as the growth advances, as it is much subject to insect pests. I have never tried it in pots, but I should think that strong plants in 48's or 32's (properly trained) would be useful.—*PTERIS*.

## ROYAL BOTANIC SOCIETY.

MAY 19TH.

THE first summer Show of the season was held as usual in the large marquee at Regent's Park, where the plants were most tastefully arranged. Orchids and Roses constituted the chief features, and the former have seldom been so well represented at the first summer Show. Stove and greenhouse plants and Azaleas were not quite so numerous as we have seen on some previous occasions, but the specimens were well grown and evenly trained. The weather was not favourable, being wet and dull throughout the day, which lessened the usual attendance of visitors.

**ORCHIDS.**—A magnificent bank of Orchids was formed by the leading exhibits in the classes provided. Mr. J. Douglas, gardener to F. Whitbourn, Esq., Great Gearys, Ilford, was first with twelve specimens, admirable examples of good culture, comprising *Cattleya Mossiae* with over thirty flowers, *Oncidium ampliatum majus* with eight fine panicles of flowers, *Cymbidium Lowianum* with two racemes of about thirty flowers each, *Odontoglossum vexillarium* splendidly flowered, *O. crispum* five spikes, *O. citrosimum* three spikes, the flowers of bright rosy colour, two excellent plants of *O. Roezli* grandly flowered, *Dendrobium Wardianum*, and *Cypripedium Laurencianum*. This was a beautiful fresh collection of plants, and they were much admired. Mr. F. G. Hill, gardener to H. Little, Esq., The Barrons, Twickenham, was second; a large *Dendrobium thyrsiflorum* with about two dozen racemes, *Lycaste Skinneri*, and *Laelia purpurata* being amongst the best. Mr. C. J. Salter, gardener to J. Southgate, Esq., Selborne, Streatham, was third, *Masdevallia Veitchi majus* with eleven fine flowers being especially notable. *Dendrobium nobile*, *Masdevallia ignea*, *Dendrobium Falconeri*, and *Odontoglossum polyanthum* were also fine plants.

In the nurserymen's class for twelve plants Mr. J. Cypher, Cheltenham, was first with vigorous well-flowered specimens of *Laelia purpurata*, *Cattleya Skinneri oculata*, *Dendrobium thyrsiflorum* very large, *Vanda suavis*, *Dendrobium crystallinum*, *Odontoglossum crispum*, *Cypripedium biflorum*, *C. villosum*, *Cattleya Mossiae*, *C. Mendeli*, *Odontoglossum citrosimum*, and *Cypripedium Lawrenceanum*. Mr. H. James, Lower Norwood, was a close second, *Laelia purpurata* bearing twenty grand flowers being especially handsome. *Dendrobium Jamesianum*, with twenty-flowers, was also very fine, with *Cattleya Mendeli* well flowered.

For twelve Orchids (single specimens) Mr. J. Cypher was again first with well-grown *Cattleyas* and *Laelias*. Mr. H. James was a close second with an interesting collection. Mr. J. Douglas was a good first in the corresponding amateurs' class, followed by Mr. S. Cooke, gardener to De B. Crawshaw, Esq., Rosefield, Sevenoaks, who had two fine varieties of *Odontoglossum crispum*, one named *gigantea* of great size. Mr. W. May, gardener to F. C. Jacoby, Esq., Amhurst Park, Stamford Hill, was also awarded an equal second prize for well-grown plants of *Odontoglossums*, *Cattleyas*, *Laelias*. Mr. W. May was awarded a large bronze medal for a pretty collection, a similar award being made to Mr. T. Banks, gardener to E. Gotto, Esq., Hampstead, for a group of Orchids, and a small silver medal to Messrs. Hugh Low & Co., Clapton, for some choice varieties of *Cattleya Mossiae*, one named *splendidissima* well deserving its name, the flowers of wonderful size and colour. A bronze medal was also awarded to Mr. D. White, gardener to Mrs. F. Watson, Redlees, Isleworth, for a grand specimen of *Cattleya Mossiae* 4 feet in diameter with over sixty flowers and buds.

**ROSES.**—Messrs. Paul & Son, Cheshunt, were first with twenty Roses in pots, admirably grown specimens of medium size, representing some of the leading exhibition varieties with thirty to forty flowers each. Mr. C. Turner was a close second, with beautiful fresh well-flowered plants. Madame G. Luizet, Avocat Duivier, Juno, Countess de S. renne, Dr. Andre, Innocenti Pirola and Madame Lacharme being the best. Mr. Rumsey, Waltham Cross, took the third place with small but very neat plants. Messrs. Paul & Son were first with nine large specimen Roses, as fresh and well flowered as could be wished. Messrs. G. Jackson & Son, Woking, followed very closely. Mr. Rumsey was third. Mr. P. Perry, gardener to W. G. Rowlett, Esq., The Woodlands, Cheshunt, was also a good exhibitor in the class for six Roses.

**STOVE AND GREENHOUSE PLANTS AND AZALEAS.**—Mr. J. Cypher was the premier exhibitor in the nurserymen's classes, being first both with twelve and six specimens, huge *Azaleas*, *Anthrinnums*, and other standard exhibition plants, which Mr. Cypher grows so well. Mr. H. James was second with twelve large trained specimens, and he was also second with six plants of similar merit. Mr. J. F. Mould, Pewsey, was third with twelve medium size but good plants.

In the amateurs' class for six stove and greenhouse plants Mr. Chapman, gardener to J. Spode, Esq., Hawkesyard Park, Rugeley, was a good first, showing some excellent specimens, *Tremandra ericaefolia* being especially fine. Mr. C. Rann, gardener to J. Warren, Esq., Handcross Park, Crawley, was second, his *Tetratheca ericaefolia* being in magnificent condition. Mr. W.

Chapman was first for ten specimens with magnificently trained plants *Dracophyllum gracile* and *Ixora Dixiana* being in capital condition. Mr. G. Wheeler was second, and Mr. Butler was third.

The grandly flowered plants from Slough gained Mr. C. Turner the first prize for six *Azaleas*, 5 or 6 feet high, as much in diameter, and loaded with blooms. Duc de Nassau, Chelsoui, and Comtesse de Flandres were very notable. Mr. Turner was also first with twelve *Azaleas*, smaller, but equally bright plants. Mr. J. Cypher and Mr. Mould secured the prizes for six Cape Heaths, healthy freely flowered plants.

Pelargoniums were a bright feature, Mr. C. Turner as usual securing the leading prizes in the nurserymen's classes for Show and Fancy varieties, followed by Mr. J. Cypher. In the amateurs' classes Mr. D. Phillips, gardener to R. W. Mann, Esq., Langley Broom, Slough, was first, followed by Mr. Hill.

Ferns were shown by Mr. J. Douglas and Mr. R. Butler. Mr. H. James had the best six foliage plants, showing his usual fine specimens. Mr. Rann had the best six foliage plants in the amateurs' class, large specimens of *Crotons* and *Palms*. The hardy and Alpine plants from Messrs. Paul and Son, Cheshunt, T. S. Ware, Tottenham, and J. Douglas, who were awarded the prizes in the order named, included some attractive plants.

Miscellaneous exhibits were numerous and attractive. Messrs. J. Veitch and Sons, Chelsea, had a group of novelties, including some beautiful *Gloxinias*, *Anthuriums*, *Lilium longiflorum*, *Hydrangea paniculata grandiflora*, the graceful *Rosa lucida*, "Rose Button," and varieties of Japanese Maples, with several novelties that were certificated. A large silver medal was awarded to Mr. B. S. Williams for a large and handsome group of Orchids and fine-foliage plants, comprising many varieties and valuable rarities. Messrs. Wm. Paul & Son, Waltham Cross, contributed a charming group of Roses and Ferns most effectively arranged and representing a large number of varieties. (Silver medal.) Messrs. G. Henderson and Son, Pine Apple Nursery, Nursery, Edgware Road, were awarded a silver medal for a group chiefly composed of fine-foliage plants with a few Orchids, *Anthuriums*, and *Pinguiculas* to brighten the display. Messrs. J. Laing and Co., Forest Hill, were awarded a large silver medal for an extensive group of *Begonias*, Orchids, Ferns, *Palms*, *Caladiums*, and other choice plants. Messrs. W. Cutbush & Son, Highgate, arranged a tasteful group of greenhouse plants, bright and interesting.

A bronze medal was awarded to Mr. T. S. Ware for a large group of hardy flowers, bunches of *Ixia crateroides* being very bright. A similar award was also granted for a group of Tree Paeonies of many colours. Mr. C. J. Salter had a large group of *Calceolarias* representing an excellent strain, the flowers large and brightly coloured (large bronze medal). Mr. J. Wiggins, gardener to W. Clay, Esq., Elm Villa, Kingston, showed a group of *Cinerarias* and *Pelargoniums* (bronze medal). St. George's Nursery Company, Hanwell, contributed a group of *Calceolarias* (large bronze medal). Messrs. H. Lane and Son, Great Berkhamstead, had a collection of hardy *Azaleas* (bronze medal); and a similar award was made for a group of *Rhododendrons*. Mr. J. James, Woodside, Farnham Royal, Slough, was awarded a small silver medal for a group of exceedingly fine *Calceolarias*, the plants dwarf, compact, and grandly flowered. Mr. D. Phillips had a small group of *Pelargoniums*, well-flowered plants (bronze medal). Mrs. Harry Turner, Langley, was awarded a bronze medal for a box of twelve grand *Maréchal Niel* Rose blooms, wonderfully fine in size and colour.

Botanical certificates were awarded as follows:—To Mr. J. Douglas for *Aeranthus Leonis*; to J. Veitch & Sons for *Phoenix hybrida*, *Rosa lucida* Rose Button, and *Ulmus Dampieri aurea*; to Mr. B. S. Williams for *Alocasia regina*, *Laelia bella*, *L. Russelliana*, and *Oncidium tetracopsis*; to Mr. J. Douglas for *Cattleya Mossiae Silvia* and *Odontoglossum vexillarium Silvia*; to Messrs. H. Low & Co. for *Cattleya Mossiae splendidissima*; to Sander & Co. for *Odontoglossum Ruckerianum*, and to Henderson & Sons for *Alocasia regina*.

Floricultural certificates were awarded as follows:—To Mr. P. Ladds for Zonal *Pelargonium* Queen of the Whites; Messrs. J. Veitch & Sons for *Rhododendron* President and *Brookianum*. Messrs. J. Laing & Co. for *Begonia Incendie*, *Begonia Queen Victoria*; Mr. T. S. Ware for *Paeonia Moutan* Lord Macartney, *Madame de Vitry* and *Carolina*.

## HARDY FRUIT GARDEN.

BEFORE the full pressure of summer work is upon us it will be well to see that our arrangements for the care and training of young fruit trees are so complete as to insure success. Bearing in mind that perfection of form can be had without any loss of fruitfulness, we are bound to do all we can to train our young trees with precision, in view of eventually rendering them objects of beauty, independently of the fruit we hope to have from them. This can only be done while the growth is young and pliant, and therefore it is then that our most anxious careful attention must be given to the work. How frequently do we meet with failures in the form of pyramidal fruit trees! Either they have the serious fault of weak abortive branch growth, or bareness of the stem at bottom, or they are overcrowded with branches, or the form is one of squat ungainliness—a sort of nondescript—that is, neither bush nor pyramid. Yet the chief attraction in a pyramid should, before all things, be found in its symmetrical outline. For example—we have pyramids of 4 feet diameter at base, and

some 7 to 8 feet in height, and we have others 10 feet in diameter at base, and 15 feet high, that are equally symmetrical and ornamental. It is undoubtedly right to retard the upward growth of the centre of the tree till the lower tiers of branches have such a good start that plenty of sap will be diverted into them to sustain health, vigour, and fruitfulness. Keep every branch far enough from the others to afford free admission of light and air to every part of it, for remember the legitimate purpose of the growth of a fruit tree is to bear fruit. To this end also the lateral growth of fruit-bearing spurs should not be crowded thickly together. Cordons and palmette verriers have admirably supplanted the faulty old horizontal espalier. The chief thing demanding early and close attention in training palmette verriers is to give the bottom branches a good start. The full importance of this is realised as soon as we see that the end of every branch is upon a common level, filling the space once devoted to the top branch alone of the horizontal espalier. Diagonal cordons answer best as espaliers, because of the greater length of stem which an angle of 45° affords. This is an attractive, profitable, and elastic method of fruit culture, alike suitable for large or small gardens, the trees being only 18 inches apart. The garden must indeed be small where space cannot be found for a dozen or two of them. We recently saw a small garden where the whole of the bush fruits were trained to strained wires espalier fashion, and certainly we never saw bushes with better promise of an abundant crop of fruit, and the appearance was singularly neat and attractive.

#### FRUIT FORCING.

**PINES.**—Sunshine has of late helped considerably. Such seasonable influences should be fully utilised, as under such conditions the growth in these plants may be advanced more expeditiously and with safety, provided proper care be given to the ventilation, which in sunny weather should be attended to early in the morning, because in Pine cultivation too much moisture cannot be had within the house and the plants, provided it is dispelled off the leaves of the plants before powerful sun acts fully upon them. In order to maintain a genial condition of the atmosphere freely moisten all available surfaces about the houses whenever they become dry. Especially is this necessary just before closing time, which should be sufficiently early in the afternoon to keep the temperature at 85° to 90° for a considerable time afterwards. In dry weather syringing will be needed daily, but this must be regulated by the condition of the house and plants. In the case of the plants the best criterion is the axils of the leaves. Those during the growing season should never be allowed to become quite dry, because many feeding roots exist around the stems of Pine plants which only derive support from the water in the axils of the leaves. Be careful at this season not to allow any plant to suffer for want of water, but give an adequate supply, and in all cases with some stimulant such as guano, but be very careful to avoid giving it too strong. Let the requisite attention be given to shading; the thinner the material is for the purpose the better, as only enough shade is required to prevent the sun scorching the leaves or fruit. Dispense with fire heat as much as possible, but a little will still be necessary in the succession as well as fruiting departments. Continue giving attention as occasion requires to the removal of all surplus suckers, leaving only one or two on each plant for stock, and close at 90° in the fruiting department. Recently potted plants should have a liberal supply of heat, 90° to 95° at the base of the pots will induce roots to take hold of the soil quickly.

**VINES.**—*Houses of Ripe Grapes.*—The temperature should be lower, but sufficient fire heat will be necessary to prevent its falling below 60°, and to allow of a free circulation of air, but sufficient moisture must be present in the atmosphere to prevent injury to the foliage from drought or the spread of insects. Examine the borders, and if sufficiently moist let them be covered with some dry non-conducting material to prevent evaporation, always bearing in mind that Vines carrying ripe Grapes in June and July require more water than they do in the autumn. If water is necessary afford it in the early part of a fine day. Allow a moderate extension of the laterals, which will keep the roots active, prevent the foliage ripening prematurely, and by shading assist in the Grapes retaining their colour longer, as ripe Hamburgs lose colour exposed to the direct rays of the sun for some time, and which must be prevented by shading with a double thickness of herring nets run over the roof lights.

*Grapes Stoning.*—Keep the temperature steady at night—60° to 65° being sufficient, as it is a process that requires time, and the roots are better in advance of the demands than the lacking of supplies by the berries for the completion of the most exhausting process to which Vines are subjected. The borders must be kept well supplied with moisture passed through a rich surface mulching, or, if this be not present, liquid manure should be given, and always in a tepid state, as any check now given the roots may induce shanking. If there is any fear of the latter allow lateral extension so as to accelerate root-action, as shanking is almost always a result of turpid roots. When the stoning is completed give a thorough soaking of tepid water or liquid manure, according to the requirements of the Vines, and mulch with some light non-conducting material. Maintain a moderate degree of moisture in the atmosphere after the Grapes begin to colour for the benefit of the foliage, and to insure the swelling-off of the berries. Afford a gentle circulation of air constantly, increase it early in the morning and with advancing sun, and reduce correspondingly with the declining sun heat, closing sufficiently early to retain sun heat.

*Late Houses.*—Keep the stopping and tying regularly performed, and aim at an even spread of foliage all over the trellis by laying in laterals as long as there is space for full development without crowding. Thin out the berries liberally, giving preference to medium-sized compact bunches,

which finish much better than large loose ones, the berries of the latter having long footstalks. Examine the borders, and top-dress in accordance with the requirements of the Vines. If young and full of vigour, and the borders rich, a slight dressing of short-horsedung will be found most suitable; but if poor in soil and the Vines not very vigorous a good mulching with cowdung will be found highly beneficial.

By this time the thinning of the main crop of Muscats will have been brought to a close, and the borders will be in a fit state for mulching with good manure, and need copious supplies of water or liquid manure. It will be necessary to keep the external borders well covered with leaves or litter to prevent the escape of moisture, and on light soils the application of water or diluted liquid manure may be necessary if the weather be dry.

Lady Downe's, Mrs. Pince, Black Muscat, Black Morocco, and some of the white kinds will now be in flower, and they should be cross-fertilised with Hamburg pollen, it being a good plan to have a Hamburg Vine in flower for that purpose. Muscats are very often associated with late thick-skinned Grapes; and well as the thick-skinned do up to a certain stage in the same temperature as Muscats, the temperature necessary for the proper finish of Muscats is too high for the black varieties, and they often remain deficient in finish. To grow the finer black Grapes they should be kept out of the Muscat house, and have the benefit of a long period for making and maturing their growth and crops. Gros Colman, though it will stand any amount of heat, suffers in such in foliage under bright sun, and can only be obviated by a circulation of air, and allowing a long season of growth.

*Lifted Vines.*—Look well after Vines that were lifted last autumn as well as newly planted young ones, and encourage new roots to find their way to the surface by the use of good stable manure as a mulching. Give the tops generous treatment, and encourage free growth by closing early in the afternoon with plenty of sun heat and atmospheric moisture. Do not exceed a temperature of 60° by night until the roots have taken freely to the soil. Disbud lightly, and stop side shoots at once to secure plump buds, and then allow the laterals to ramble over every part of the trellis.

Afford air more freely to early Vines in pots intended for fruiting next spring, and syringe the foliage to keep it free from insects, as future success is made or marred by the preservation or premature destruction of the main leaves.

#### PLANT HOUSES.

*Greenhouse Rhododendrons.*—The majority of these plants will have flowered, even if they have been subjected to cool treatment during the winter and spring. All that require repotting should be attended to at once, using for a compost good fibry peat with a liberal dash of coarse sand. The pots used should be clean, well drained, and the new soil pressed firmly round the sides of the ball. Care must be taken that the soil is in a satisfactory state for moisture when potted. These plants must be very carefully watered until the roots are working freely into the new soil. Water should be withheld as long as possible after potting, but on no account should they be allowed to suffer during the growing season by becoming dry at their roots; on the other hand, over-watering will prove detrimental. The pots should be stood on some moisture-holding material in the greenhouse or other structure where the house can be kept moderately close and the atmosphere moist. The stage, pots, and plants should be syringed at least twice daily. Under this treatment they will quickly start into growth, which must be encouraged, for it is important to complete it as early in the season as possible if a good supply of flowers is anticipated. They should be shaded from the strong rays of the sun during the time they are making their growth.

*Hybrid Perpetual Roses.*—Plants that have been forced and thoroughly hardened may now be turned out of doors. They must be stood or plunged in a warm sheltered position for a few weeks, and it may prove necessary to protect them occasionally from the effects of cold winds or frost. For this purpose two or more rows of plants may be arranged together, so that stakes can be placed into the ground on each side and tied together at the top, so that a length of tiffany can be placed over them without pressing on the plants. Secure a few strings to the tiffany, so that it can be fastened to the stakes to prevent winds blowing it off. If No. 3 tiffany is used a good per-centage of light will be admitted to the plants, even if it is thought wise to keep them covered all day. For the first week after turning them out it will be wise to cover them at night. The foliage must be preserved healthy and fresh, then good results may be looked for another season, which can scarcely be expected if the foliage is destroyed early in the season. These plants should be well syringed on the morning of fine days when they are uncovered.

Tea varieties growing under glass must now be ventilated liberally whenever the weather is favourable. When the blooms are expanding, the blinds, if fixed to the house, may with advantage be used for a few hours to prevent the flowers opening too rapidly. The temperature will now rise by sun heat very high, and if not liberally ventilated they will be attacked by red spider. The syringe must be freely used twice daily, and if attention is paid to watering, the foliage may be kept free from insects. Young plants that have been struck from cuttings this spring must be potted as they require more root room. They must be fully exposed to light in a growing temperature, and the flower buds removed as they appear.

*Daphne indica.*—More of these plants are ruined by being kept in the greenhouse than by any other cause. They cannot be kept too cool, and even during the winter they are quite safe when plunged in coal ashes in a cold frame. They should now be plunged in a cold

frame, if they are not in this position, where they will receive plenty of light without being fully exposed to the force of the sun. The atmosphere about them should be kept moist, and not allowed to suffer by an insufficient supply of water at their roots. At the same time the soil must not be saturated, or the leaves will turn yellow and fall. When growth has been completed they should be plunged in a sunny position outside to thoroughly ripen their shoots, then flower buds are certain to form at the extremity of every one.

*Tree Carnations.*—The earliest-struck plants of these will be well established in 3-inch pots, and ready for transferring into others 3 inches larger. From this stage they should be grown on cool in a cold frame, giving them plenty of air on all favourable occasions. Directly they are rooting freely into the fresh soil they should be carefully hardened and plunged outside in an open position. Failure is certain if these plants are drawn up weakly in a close atmosphere. Cuttings first rooted should be placed in 3-inch pots and allowed to become established in gentle heat, then hardened to cool frame treatment. Cuttings may still be struck from plants that have been growing in a cool airy place. They will root freely under handlights in a warm house if kept air-tight and shaded from the sun. Three or four cuttings at this season should be inserted together in small pots, and then shifted without disturbing them. These useful plants do well in a compost of fibry loam three parts, the other being composed of leaf mould and sand. To this about one-seventh of decayed manure may be added.

*Chrysanthemums.*—Plants required for the production of large blooms or good-sized bushes should now be ready for removal from 6-inch pots into 10-inch pots. They should be thoroughly hardy, so that they may with safety be turned outside as they are placed into their largest pots. Provision for a time should be made for shielding the plants from cold cutting winds, or their foliage will be browned and very much cut, and the plants seriously checked in consequence. Late-flowering varieties such as Princess of Teck and others may be transferred into 6-inch pots, and occupy the frames for a time from which the earlier plants have been removed. A good quantity of different sorts, especially Pompons, may now be rooted, and these will make capital decorative plants in 7 and 8-inch pots. A number may also be rooted for planting outside to yield strong robust cuttings in July for flowering in 3 to 5-inch pots. For this purpose select free-flowering varieties such as Elaine, James Salter, Mrs. Dixon, Sœur Melanie, and others that are certain to flower well.

## THE BEE-KEEPER.

### INTRODUCING QUEENS.

WHEN we consider the life-history of the bee it is sometimes difficult to know which to admire most—its wondrous wisdom or its fatal folly. At times it would seem to possess the power of reasoning, at other times it seems deprived of the slightest evidence of instinct. Take for instance the behaviour of bees when deprived of their queen. One would imagine that they would only be too thankful to accept the first one offered to them; but, on the contrary, they will frequently sting her to death, or suffocate her by balling, even when she has been caged for forty-eight hours. It sometimes happens in the early spring, if we have not been careful to see that we have none but young queens, that the exertion of laying eggs has proved too much for the queen after her winter's rest, and she dies worn out, or becomes a drone-breeder.

Now if this happens before drones have been hatched any attempt on the part of the bees to rear queens must prove abortive, but even then they sometimes will not accept a strange queen; and the older the bees, especially those who have lived through the winter, the more difficult it is to introduce a queen.

With newly hatched bees there is much less difficulty, as they seem to take more readily to a strange queen; and when we have a valuable queen we find it most advisable to make an artificial swarm, place this on a new stand some distance away from the old stock, when the larger number of the old bees will return to it, leaving the young bees in their new abode. We place two or more bars of brood with the swarm, and then cage the queen for forty-eight hours, when the young bees will gladly welcome her. This delay seems a loss to the hive of egg-laying; but as the bees have more time to devote to the eggs which have been laid, and the brood is hatching out while the queen is caged, the original stock is not deprived of such a large number of bees, as a 3 lb. swarm with two bars of brood is often as good as a 5 lb. swarm without.

The modes of introducing queens may be divided into two classes—(1) direct, (2) indirect.

In the first the mode of procedure is as follows:—If there is a queen which we wish to remove we take her out of the hive, and then insert the new queen with her attendant bees on a bar in the middle of the brood-nest of the hive from which we have taken the queen, then close up the hive with the carpets, &c., and the operation is completed, the theory being that the queenless bees

take to the new queen and her workers, because they are not excited or nervous, but seem thoroughly at home.

If the queen to be introduced is on an odd frame we must first put her on a frame of the same size as the hive in which she is to be placed, and if we want to introduce her and her workers it is advisable to let them be in a nucleus for a few hours, and especially if they have come any distance. They will soon get quiet, and then can be introduced as before, or the queen can be introduced on a comb by herself if there is any uncapped honey or syrup.

In fixed hives the bees must first be all driven out, as in artificial swarming, a little syrup sprayed over the combs, the old queen removed, and then the bees are shot down on to a board; and as they ascend to the hive, which has been raised from the floor-board, the new queen is allowed to go up with the crowd.

In the indirect mode of introducing, the old queen having been first removed, the new queen is caged on some unsealed honey, and then placed in the middle of the brood-nest, a pipe-cover cage being used. This is made of a piece of perforated zinc, about 1½ inch wide and 4½ inches long, the ends being soldered together; one end of the tube has a circle of perforated zinc 2 inches in diameter soldered over it, and the cage with the queen is twisted into the comb till it reaches the midrib. There are various other kinds of queen cages, but the pipe-cover is the one we always use, as it is very inexpensive and effectual.

Unless obliged we do not attempt to introduce queens either in the early spring or late autumn. When breeding is going on, and honey coming in, with proper precautions queens can be safely introduced, and though we have had sometimes to cage and recage a queen for seven or eight days, as a rule forty-eight hours is quite long enough, and with young bees twenty-four hours; and we generally release the queens late in the afternoon. Bees are kittle cattle, no method as yet has been found to be infallible, and we have often introduced a dozen queens successfully, and then though taking the same precautions lost the next two or three.—A SURREY-SHIRE BEE-KEEPER.

### PLACING AND REMOVING SUPERS.

NOTWITHSTANDING the extreme cold the bees have been very active collecting water, but entirely neglecting peameal since the two good gathering days on the 6th and 7th inst., thus proving bees are not the stupid creatures, gathering more pollen than is necessary to their wants, as is accredited to them by some. On the other hand I think them very wise insects when allowed to follow their own course, and the fool has to be searched for somewhere else than in a hive, although he may be found near it.

I have said the cold weather has been disastrous to the bees, they lie dead in great numbers near their hives; but as I provide my bees with water near them they may not have ventured far away, and the loss may be all visible. Those who do not attend to keeping their bees supplied with water near their hives must have lost many bees.

I observe that although most of my bees have been busy collecting water these cold days, not a pure Carniolian has ventured out. Some may think this a defect in these bees, but I am inclined to think it a property; because if the preserving of bees is the way to success, the Carniolians seem to possess this property naturally.

With all the drawbacks of the season, I am looking forward to the time, which is near, when supering will have to be attended to. In districts where Plums are plentiful a week hence will commence the season, if fine, for both swarming and supering. The former subject need not be discussed here whether it or the non-swarming principle is most profitable. That depends to a great extent on whether the bee-keeper desires to increase his stocks, and whether the season will be a short or a long one. If the former, then the non-swarming system will undoubtedly be the one to carry out. If the season is promising, full-sized tiering supers will give the greatest return. These and every other sort should be kept close and well wrapped up. Small supers with divisible combs holding about 5 lbs. each are what I can sell easiest, and cost little or nothing for packing for market, and are more easily managed in every respect than sections, and the bees take to supers more readily than they do sections—an important matter in bee-keeping.

Many plans have been devised for placing sections in hives. In 1876 I exhibited at Edinburgh a crate similar to the Benthall crate. In 1877 I sent out a great number of hinged frames for sections and some thousands of crates in no way different from the Benthall crate. I have about a dozen inquiries regarding the invention of bee appliances and their inventors. One of these is from my friend Mr. A. Cameron, Blair Athole, and I observe at page 141 "J. H." supports that gentleman's opinion that he was the first to think of the crate in question. I will not dispute it, because Mr. Cameron and myself were often meeting and exchanging ideas, and he was the first to order a quantity in 1877, so in the absence of more proof he deserves the honour.

I observe in the *British Bee Journal* drawings by Mr. Blow of a swarming box for the purpose of taking bees from high trees, used on the continent, "but not in this country." I obtained a first prize for a similar one in 1876, and had one in use long before that. I describe it in my Essay. Another drawing in the same journal is that of a large cage used in joining the queen and nucleus of bees to another hive. This, too, I have used for a quarter of a century.

But to the crate, seeing that Scotland has the priority of the invention, as it has in most things pertaining to common-sense bee-keeping. For the benefit of bee-keepers I will explain the plan I placed the sections in the Perthshire-Lanarkshire crate. When sections are placed with their ends close to the crate, the bees do not fill the sections compactly to the ends; but when they hang in the crate similar to frames, having a quarter of an inch between them and the walls, they more readily fill the section compactly. I made my section from 1½ to 2 inches broad, all in one breadth, and along each end of the section I nailed a light fillet of wood and allowed it to project one-eighth of an inch at each end; this served as a distance guide. Then along the sides of the crate I nailed another fillet to suspend the sections on, not unlike the plan for reversible frames. When so placed they are easy of manipulation, and the bees fill them neatly, and they can be sent to market with a greater certainty of safety than when packed hard to the crate. Instead of nailing a fillet on, nails alone will suspend the sections, but are not so satisfactory as the above plan on account of the absence of the distancing between the sections by the fillet. There are other ways of placing the sections, but the above plan was the only one that satisfied me. Queen-excluder, zinc, and separators are both abominations in the hives, and are unnecessary.

Now is the time to be careful that the supplies do not get short in the hive. At the time we put on supers for obtaining a surplus of honey is the very time bees are liable to die through a scarcity of meat. It is, therefore, to be hoped that casualties will not be increased through overlooking giving syrup in time, nor yet causing the bees to lose themselves by flying about through injudicious stimulative feeding.—A LANARKSHIRE BEE-KEEPER.

#### TRADE CATALOGUES RECEIVED.

Edmund Philip Dixon, 57, Queen Street, Hull.—*Catalogue of New and Choice Plants and List of Chrysanthemums.*

Follows & Bate, Dutton Street, Manchester.—*Illustrated Catalogue of Lawn Mowers, Garden Engines, Syringes, &c.*

J. Carter & Co., 237 and 238, High Holborn.—*List of Choice Plants.*

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Books (W. G.).**—If by the "cheapest" work you mean one that you can obtain for a small outlay you may invest in Pearson's "Vine Culture." It is brief, plain, and sound, price 1s. 1d., post free, from this office.

**Premature Chrysanthemum Buds (Chrysanthemum).**—Remove the buds as soon as they form at this season of the year, but do not top the plants. Your letter, with Mr. Molyneux's reply, will be published in an early issue.

**Weevils on Peach Trees (Constant Reader).**—Your trees are attacked by the destructive weevil *Otiorynchus sulcatus*. See what is said on catching them in reply to another inquiry. After you have cleared the trees tie some cotton wool round the stems or anything else up which the enemy crawls, and smear it now and then with tar.

**Dissolved Bones (J. Button).**—You cannot do better than apply the manure as a top-dressing and water it in. About half a teaspoonful to a 6 or 7-inch pot is sufficient for most plants that require more support than the soil affords. About 2 ozs. to each square yard is a good dressing for lawns and outdoor crops. Your letter is very brief and vague, the reference

to "the dissolved bones" implying that you have a supply, and desire to know how to use the manure. If, however, you wish to know how to dissolve bones, you will find the information on page 263, April 1st, 1886.

**Planting Vines (C. C.).**—You cannot do better than plant Black Hamburghs entirely in your early house for forcing; another house with Gros Colman; and if you mix them with any other kind we advise Muscat of Alexandria. The former does best in the temperature of a Muscat house, and there is never a difficulty in disposing of good examples of the last named. In your third house plant principally Alicante. You might try a few canes of Gros Maroc, which would be ready for cutting before the Alicantes. It is a noble-looking Grape, and would probably take well in the market. It is a strong grower and needs plenty of space for the development of its foliage.

**Peach Leaves Perforated (A. G. P.).**—The perforations are made by some weevil eating the leaves while young, their size increasing with the enlargement of the leaves. A white cloth placed beneath the trees after dark, and the tree shook sharply would probably cause the weevils to be taken, but care must be taken not to make any noise, and to operate in the dark, as they fall to the ground on the approach of light and with a noise, and so escape detection. The cause of the blossom buds falling is no doubt due to imperfect bud-formation, probably deficiency of water at the ripening and resting periods. Prolonged cold is very much against the setting of Peach blossoms, and sometimes proves fatal through the imperfect development of the organs of fructification.

**Tomatoes in Open Quarters (Tomatoes for Profit).**—Tomatoes used to be grown much more extensively in open quarters near London than they are now. They were planted a yard apart or a little more, by some growers 4 feet. One stem only was secured to a stake, and when four or five bunches of fruit were set no more growths were allowed to extend, and even some of the large leaves were removed to prevent the fruit being unduly shaded. We have seen several acres of them, but the practice indicated is now practically discontinued in the same district, the "disease" having ruined so many crops; still they are grown to a limited extent in favourable positions, and when the crops are good they pay cultivators well. The crop, however, is regarded as a "risky" one.

**Boiler (Horace).**—A plain wrought iron rivetted saddle boiler is good, not liable to go wrong, and, if properly set, is very efficient. The check-end saddles are, however, improvements upon the old plain saddle; any extra first cost being amply repaid in the economical consumption of fuel through the increased efficiency of the boiler. Terminal end saddles are also efficient, as the full force of the furnace is concentrated on the crown and end of the boiler where the flow pipe is situated. We advise one of the improved forms of saddle, a check end and terminal saddle not being much more complicated than a plain saddle, and properly made are quite as durable. They can be had in either cast or wrought iron. We prefer the latter. A steel one would be still better, as the thinner the boiler plates the more quickly the heat is abstracted by the water from the furnace.

**Weeds in Lawn (Inquirer).**—The weed you have sent is commonly called Crowfoot, a wild *Ranunculus*, and it grows freely and spreads quickly in damp soil. The mowing machine will not destroy it. You must either dig out the weeds or kill them with acid, one drop of either sulphuric or carbolic acid placed in the heart or crown of each being effective. It is best kept in a stone blacking bottle with a wire handle, and can be applied with a stick with a few notches cut in it near the end, these hold the acid, enough being secured at one dip for destroying three or four plants if close together and the user is expert. It must be applied right in the centre of the weeds alone, not rubbing the stick on the grass, boots, or clothes, as the acid will burn everything it touches. In this way the weeds may be destroyed far more quickly than by digging them up, but if there are only a few of them this effective mode of riddance may be adopted.

**Planting Flower Bed (C. E.).**—Viewed from the ends your proposed arrangement would be fairly effective, but instead of bars across the bed we should prefer to plant each sort in circles, which would be effective from all positions. We could have better expressed an opinion if you had stated the dimensions of the bed, but most probably nine circles would be ample, the central one being filled with Cannas and the others grouped as proposed in your arrangement. The border or edging can still be of light-leaved Pelargoniums, and the remaining spaces filled in with either a good *Ageratum*, such as Cannell's Swanley Blue, or, better still, *Heliotrope Florence Nightingale*. If you still prefer your own arrangement, either of the last mentioned would be suitable for the ends. In any case, each sort used would have to be kept within bounds, or they are liable to overrun each other and a confused mass is the consequence.

**Camellias not Expanding (C. H. S.).**—The cause of the Camellia buds not fully expanding is due to the young growths taking the lead. This is often the case with late-flowering varieties or those that are unduly retarded. In such cases it is a good plan to pinch off the young shoots as soon as they appear, which will throw all the resources of the plant into the development of the flowers. The young growths pushing so freely before the flowers have fully opened is due to the luxuriance of the trees. From this cause alone they often fail to flower satisfactorily. We advise you to feed the trees less freely for a time, and induce the formation of hard short-jointed growth by the admission of abundance of light and air. When Camellias are vigorous, the growths starting after the blooms are cut attain quite sufficient strength for forming flower buds and perfecting blooms; hence we do not hesitate to nip off those growths that take the sap from the flower buds. It would not do to similarly suppress the growth of weak plants.

**Woodlice and Mushrooms (S. L. B.).**—You ask "What harm these pests do on Mushroom beds?" The chief harm is they eat the Mushrooms. When beds "swarm" with woodlice they leave very few Mushrooms to develop for the owner. We do not know that they eat "the white threads of spawn just as it comes through the soil before the tiny Mushroom is formed." When Mushrooms form there they must be "tiny." Fine Mushrooms form in or beneath the soil, not from mycelium on the surface, and when "white threads" cover the surface like network it is usually an indication of the covering being too thick and damp, "drawing out" the spawn. We like to see the soil lifted up by great masses of Mushrooms below, and when we see the surface of the bed rise and crack as if from the force of a

miniature earthquake we know what is coming—fat heavy Mushrooms, weighing not unfrequently from half a pound to a pound each. Those are larger than we prefer, but cannot always be prevented. We have not tried sprinkling Mushroom beds with pepper, but should not think it would injure them. The method of entrapping woodlice with old boards, alluded to on page 346, is equally applicable to outdoor and indoor beds.

**Carpet-Bed Arrangement (Merchant).**—What is meant by the ground-work of the plan is all the space surrounding or not occupied by the various figures of the design, which in your case would be Nos. 3, 4, 5, and 6, a single number being sufficient, as one kind of trailing or close-growing plant only is used. Planted entirely with the varieties of carpet-bedding plants you name the bed would be much too dull in appearance, whereas such beds cannot well be too bright. Further, in planting a bed of this description it may also be advisable to outline the figures with some kind of hardy plant, and this admits of the design being filled in again for the winter. If you can purchase cheaply a box of seedling Golden Feather Pyrethrum—these in preference to plants in small pots—they would effectively outline figure 2, both for summer and winter. No. 1 could be outlined with the *Santolina incana*, the centre being filled either with one *Centaurea candidissima*, and surrounded with *Lobelia pumila magnifica* or other good named sort, or five more *Centaureas* may be used if the circle is of good size, among these being mixed either *Lobelias* or *Sedum lydium*. The whole of the centre of No. 2 to be filled with *Alternanthera magnifica*, Nos. 7, 8, 9, and 10 may be lined out with *Cerastium tomentosum*, this being planted so as to form a neat narrow ring, and in the centre of each a plant of *Echeveria metallica* surrounded with *Mesembryanthemum cordifolium*. Edge the bed with *Mesembryanthemum* and fill in the groundwork with *Sedum lydium* or *Herniaria glabra*. The work must be performed very neatly, commencing with a perfectly smooth and level surface, and during the summer the outlines must be preserved by occasionally regulating and pinching back where necessary. *Alternantheras* especially should be planted rather thickly, as they seldom form much fresh growth, neither ought they to be put out before June.

**Spring-pinching and Summer-pruning Fruit Trees (J. E.).**—Undoubtedly any advocated practice should be applied intelligently, and modified as may be advisable under varying circumstances. No rule can be laid down that can be rigidly applied to every tree. The remark that you cite—namely, "Close prune spring growth, but only shorten mid-summer growth sufficiently to admit air and light freely to the spurs"—represents the practice of one of the best fruit growers in this country, and has been practised by numbers of others. It is sound in principle. If spring shoots are pinched as soon as five or six leaves have formed, and the growths of trees are so thinly disposed that the sun and air can act freely on those leaves, they develop and store nutrient matter in the spurs; but if the said shoots are permitted to extend into long branches, and these numerous, the lower leaves are necessarily imperfect, by the more luxuriant foliage above diverting the sap, and at the same time depriving the lower and weaker parts of the prime essentials of health and fruitfulness—light and air. It is obvious, then, to cut back long shoots in summer closely, and to what would under the circumstances be imperfect leaves, would not and could not conduce to the fruitfulness of the trees. After young shoots are pinched in spring one or two of the upper buds will start, and if these are permitted to extend till September, and the "midsummer growth" not shortened to "admit air and light freely to the spurs" (or leaves that perfect them), the spring pinching need not have been done, for certainly it could be of no benefit. We are not now advocating the universal pinching of spring growths, regardless of the condition and character of trees, but showing that the sentence that puzzles you embodies a sound principle. Summer pruning is only good when properly carried out; and when it leads, as often is the case, to subsequent overcrowding, it had better not have been done. When the growth of fruit trees extends and solidifies as made under the direct influence of the sun, fruit buds often form along the entire length of the young wood, not of Peaches and Nectarines only, but Apples and Pears; but then comes an important practical point. In the case of trees innumerable their allotted space is occupied, and such an extension would amount to mere encroachment. Obviously, then, it is a necessity of the case to do what you prefer—to act "according to circumstances." The rule is sound.

**Names of Fruits.**—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. (W. Reading).—Hubbard's Pearmain.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (Henry Murton).—1, *Prunus virginiana*, Virginian Bird Cherry; America. 2, *Pyrus intermedia*, Intermediate White Beam Tree; British. 3, *Polygala latifolia*, Cape Milkwort; Cape of Good Hope. (Houndswood).—*Brassia verrucosa grandiflora* (very fine); the white flower is *Chysis bracteescens*. (W. B. S.).—*Ranunculus aquatilis*. (H.).—*Citrus medica Citron*. (B.).—The Tulip is what is known as a "breeder"—one that has not broken into colours; or a reversion. It has no name. (Leadenham).—It is not the common Hemlock, but the Fool's Parsley, *Aethusa Cynapium*, which is sometimes known as the Lesser Hemlock. (B. D.).—1, *Selaginella caesia*; 2, *Selaginella stolonifera*; 3, A variety of *S. Kraussiana*; 5, *Pteris serrulata*; 6, *Selaginella Martensi*.

**Dysentery in Bees (Ayrshire).**—The reason why your bees are suffering from dysentery is most probably due to the fact that you allowed them too much room in the hive. When bees are packed for the winter they should not have more than six combs of sealed honey, and all unsealed honey should be extracted, as it tends to dysentery. You do not mention whether the sugar you use is white or brown, as the latter often disagrees with bees. If you have a spare hive remove the bees and the brood into it, rejecting any

soiled combs. See that the bees are kept warm and dry, keep them confined to a few frames by moving up the division board or boards, and feed with candy or thick syrup, 7 lbs. white sugar to a quart of water, but candy is preferable. As the weather gets warmer the bees will be able to take a cleansing flight, and if only dysentery the disease will disappear. Thoroughly clean the old hive before using again.

#### COVENT GARDEN MARKET.—MAY 19TH.

TRADE steady, with little alteration in prices. Strawberries in heavy supply, and scarcely cleared at lower rates.

#### THE FUTURE OF FARMING.

ECONOMY of time will undoubtedly receive much more attention in the future than it ever has done even up to the present, for well has it been said that life is much too short for time to be squandered in aimless efforts. Results must be achieved in the shortest surest manner, and in order to do this we must know all about the best way of doing things. Much as we have written about the value of chemical manures, yet we do not forget that they are an expensive

necessity, and we are bound to do all that is possible to avoid the purchase of them. Sheep-folding is one of our great helps in this matter; green crops for ploughing in is another, and when such crops can be obtained as catch crops either before, after, or between the regular cropping, we combine economy of time with economy of money in the best way. Take, for example, that useful crop, Winter Oats. It is generally ripe for harvest by the second or third week in July, and by the exercise of a little promptitude we may readily obtain an autumn green crop after it, which will store the soil with fertility. Or to take some of the land which was foul with twitch at the beginning of the present year, but which the dry weather at the end of April and in the first ten days of the present month enabled us to make clean. Instead of leaving it bare for a summer fallow we have sown much of it with Mustard for ploughing in for a Wheat crop, and after the first crop of Mustard is ploughed in we may repeat the process should showery weather set in.

Perhaps now more than ever it is an exception to see a clean fertile farm in the highest sense of the term. On the day previous to writing this article we travelled upwards of 100 miles by rail and road, through land most of which was under the plough, yet we saw very little evidence of really first-class farming. For mile after mile did we see indications of a want of fertility in the soil, and the contrast of some 5000 acres of well-managed crops which we went to inspect was all the more remarkable. The sad fact was but too evident that second-rate farming was the rule, and first-rate practice the exception. How much better would it be, how greatly to the general advantage, if instead of crying out for legislative help we were to set seriously to work to render the soil more productive! We must remember that it is not Russia or America with which we have only to contend in the Wheat trade. Our own colonies are pouring in supplies to this country, and India is fast assuming the lead of all of them. On May 10th we read in the *St. James' Gazette* that—"The rapid growth of the Indian Wheat trade continues. Our readers will probably recollect that last year our imports of Wheat from India for the first time exceeded our imports of Wheat from Russia. Previously Russia was our second greatest source of supply—the United States first, Russia second, and India, of late years, at some distance third. But last year, for the first time, India took the place of Russia, Russia falling to the third rank. In the first four months of the present year India has distanced Russia and almost equals the United States as a source of Wheat supply. Our total imports of Wheat from India in the past four months amounted to as much as 3,523,795 cwt., while our imports in the same period from Russia were no more than 1,381,980 cwt. There is nothing abnormal in the exports from Russia; it is in the increase of the exports from India that the change has taken place. In the four months just ended we imported one-third more Wheat from India than we had done in the corresponding quarter of the two preceding years." We believe we are correct in stating that this Indian Wheat is grown, harvested, and sent into the market at a cost of 6s. per quarter. We may, indeed, well inquire if the price of Wheat has reached its lowest level in this country. If so, is it possible in the future to continue its culture profitably? Let us not fly to extremes, but rather try to get more out of the soil, to avoid all wasteful extravagant practice, and to strive earnestly to do our work in the best way.

True economy leads us to procure pure seed of best quality, to employ skilled labour, to use the best labour-saving appliances. We must give more attention to those little matters of detail which in the aggregate so seriously affect success or failure. Use no tail corn, no seed that is not pure. Our examination of seed, both in sample and bulk, must be almost microscopic, for the use of really good seed is one of the chief conditions to success. Porous, well-drained soil, clean, well ploughed, and broken up; the

best seed, the best manure, timely culture, crops saved in good condition, careful preparation for market—all go to bring our work to a successful result. Depend upon it, the best is the cheapest in the end, because it is the most profitable. A good sample of corn is by no means so much a matter of locality as is often supposed. Good and bad crops of corn may be seen on different sides of a hedge frequently enough to convince one that we behold the results of good and bad farming. Already in our own practice this year have we had Rye up to the knee on one farm and barely half that height upon another, simply because manure was used in one case and withheld in the other; and even in so simple a matter as a catch crop of Rye for early folding the difference is a serious one. Barley may, perhaps, be an exception to corn generally, the quality of the grain being affected by peculiarities of soil; size, colour, and form all telling upon the sale of it; but much may be done even for Barley by high culture and skilful harvesting.

(To be continued.)

#### WORK ON THE HOME FARM.

The much-wanted rain began falling on the 10th, and germination of Mangold seed followed quickly. All crops have derived much benefit from showers, which were so much needed, and growth now is so quick and strong that corn generally will have become too tall for hoeing a second time where weeds have sprung up again. Much good work was done with horse hoes previous to the rain, both among Wheat and Barley, but in some fields Charlock was so thick that it had to be pulled out of the rows by hand. Land foul with couch grass has been ploughed twice, and many of the grass roots perished from exposure to the dry air and hot sun. Upon one farm where we had thirty acres of foul fallow land last year we have now only fourteen acres, and that is now ready for the Mustard seed. Clover and mixed seeds for layers, as well as for permanent pasture, have sprung up quickly, and the weather is favourable for a quick strong growth. Should showers continue there is yet time for an abundant crop of hay. Meadows having the soil well stored with fertility made considerable progress in growth, even during the recent exceptionally dry weather. The effect of sheep-folding last autumn upon grass land is now visible, especially where Cocksfoot predominates. We have one such piece of grass adjoining a field of winter Oats. The grass had old sheep fattened with corn and cake upon it in folds last autumn; the Oats after Barley had half dressings of home-mixed manures in the autumn and spring. Both grass and corn give promise of heavy crops, and we look forward with confidence to a fair profit upon our outlay there. The best piece of winter Tares we have is after Mangolds, the leaves of the Mangolds having been ploughed in immediately after the roots were cleared off the land. No doubt there is some unexhausted Mangold manure in the soil, but the leaves also imparted a valuable store of fertility to it. We have sown a six-acre field with Mangolds under such favourable conditions that we shall be curious to know the result: Peas were grown there last summer, and when the crop was harvested the land was ploughed and sown with white Turnips. Owing to the drought the seed did not germinate till so late in the season that the Turnip crop was worthless. With the Turnips Peas sprang up thickly from seed shaken out at harvest, and this green crop was ploughed in. Farmyard manure and a full dressing of home-mixed chemical manures was used for the Mangolds, so that, on the whole, we have reason to expect a heavy crop of roots, especially as the young plants have started into growth in showery weather, and we may now hope that it will lay well hold of the farmyard manure before there is more risk of drought.

#### REMARKS.

9th.—Fine, but not bright till after 9 P.M.  
 10th.—Fine, with about equal duration of cloud and of sunshine.  
 11th.—Dull and damp, with frequent rain.  
 12th.—Dull and rainy day and night.  
 13th.—Heavy rain early till 10 A.M.; showery and drizzly day; fine night.  
 14th.—Generally dull and cloudy, but with a little sunshine; showery evening.  
 15th.—Cloud and sunshine; heavy hail shower about 2 15 P.M.  
 A wet and cloudy week, with a great fall in mean daily maximum temperatures. Slight frost on Saturday morning.—G. J. SYMONS.

### ASPARAGUS.

**W**HY is not this most delicious and highly esteemed spring vegetable more extensively grown in this country? The demand for it in towns is so great that tons of bundles have to be imported from France to meet it. This French supply is highly acceptable no doubt to consumers in Britain, and the early consignments cannot be regarded as prejudicing British growers; but, on the contrary, the early dishes stimulate the taste for more, and would undoubtedly lead to a greater consumption of home-grown Asparagus if it were larger than is usually seen. It is a mistake to suppose that French Asparagus is different in variety from English. It is larger because it is grown better, and the stems are white because they have been earthed up. They can be grown as large in Great Britain as anywhere else with good culture, and be white or green at the will of the cultivator. In a few English gardens Asparagus is produced equal to the French-grown bundles, but as a rule the case is different, and it is a little humiliating to have to admit that during what may be termed the English Asparagus season French consignments compete successfully with home-grown produce in British markets; in fact, so long as the foreign produce is imported it meets with a ready sale, because it is on the whole finer than that grown at home.

Asparagus is very ill treated in hundreds of British gardens. The method of culture is wrong, and the cutting is too severe and too long-continued; hence the plants are weakened. The roots are often sodden with wet when they ought to be drier, and dry when they ought to be moist; and the plants are fed at the wrong time—namely, in the winter when resting, instead of in the summer when working. Salting and manuring Asparagus beds in late autumn often makes the ground like a puddle in the winter, and it is not at all unusual to find the growths in summer drooping from drought. That is not the way to get fine Asparagus.

Except in very wet or low-lying districts, where the water table is within 2 feet from the surface, Asparagus is better grown on the level than on raised beds. A very strong growth in summer is the great desideratum. Secure this, and fine heads will be certain to follow in the spring. A strong summer growth cannot be supported without moisture and manure, and the latter to be immediately available must be soluble. Instead, then, of piling rich solid manure over the crowns of the plants in the winter, liquid manure should be given in the spring and summer, mulching the surface after May to keep in the moisture. That is the way to get strong growth, and there is no other way in which it can be secured so well; and it is very certain that weak pale green "grass" in the summer can only produce small pipe-stem-like growths for cutting in spring. As a top-dressing for Asparagus in the summer a mixture of equal parts of superphosphate of lime and nitrate of soda, is excellent applied at the rate of 2 ozs. to each square yard and washed down to the roots. Salt

No. 309.—VOL. XII., THIRD SERIES.

may and should be given just in sufficient quantity to prevent the growth of weeds, for it is obviously useless making land rich to be made poor again by those robbers, and that is just what occurs in the case of numbers of Asparagus beds in this country.

There are hundreds of acres of land, especially near the coast, light in texture, rich in vegetable matter, moist without being swamped, in which first-class Asparagus might be grown with profit to the cultivators if they adopted a sound and generous system of management; and if a great deal more were produced at home and a little less from abroad it would be no worse for British cultivators and consumers. Very good plants can be grown 18 inches apart in rows 3 feet asunder if they are well fed, summer feeding being the most important of all points in growing this favourite vegetable in the highest state of excellence.—AN OLD GROWER.

THIS delicious vegetable does not require half the expense often incurred. These are words I have repeatedly seen as an advertisement in the Journal, and I am very much inclined to think there is a great deal of truth in them.

Now, as I have been cutting some capital heads from beds twenty years old, and this being the height of the Asparagus season, I think perhaps a few remarks on our system of management may not be out of place. In every garden where I have lived it was always the custom to give the Asparagus beds a heavy dressing of stable manure some time during the winter, and doubtless there are hundreds of gardens where this plan is carried out, but that large weighty produce can be obtained without the aid of stable manure is certain. Now, in the garden here we have no horse or cow manure, so we have to find substitutes, and these we have in earth-closet manure and house sewage.

In the autumn when leaves are plentiful we collect a large heap of these, and then get a quantity of manure from the earth closet (of which we always have a stock under cover), and thoroughly mix with the leaves, then the surface soil is thrown from the beds into the alleys, and a good dressing of the above mixture is put on as soon as possible. We always find it best to scatter a coating of soil over the top, as it keeps the leaves from being blown about; this forms the winter covering, but in addition to this we give the beds thorough drenchings of liquid manure from the sewage tank, not in the winter when the roots are inactive and the ground sodden, but now, and at intervals all through the summer when fresh roots and crowns are fast forming; this supplies them with rich food at a time when most needed.

That the above treatment will produce good results is beyond all question, for we have Asparagus rising out of the ground as large as a fair-sized walking-stick, and the flavour is excellent.—F. H. W.

[It is very rarely we see finer heads of Asparagus than examples we have received from our correspondent. They are a credit to him, and an abundant supply of similar produce is coveted both in private gardens and public markets. It is observable that both our correspondents lay stress on supporting Asparagus during the growing season. They are unquestionably right in their advocacy of supplying the plants with liquid manure from the present time onwards. The practice of covering Asparagus beds thickly with manure in the autumn, raking most of it off again in the spring, then allowing weeds to luxuriate in the summer where it yet lingers, ought to cease. We never "weed" our Asparagus beds, but prevent the necessity by occasional applications of salt, and the manure we apply is appropriated by the crop for which it is intended.]

### COLUMBINES.

AMONG the many showy and useful flowers for adorning our gardens in early summer the Columbines should always be found. They possess an elegance which only needs to be seen to be fully

No. 1965.—VOL. LXXIV., OLD SERIES.

appreciated, especially with the long-spurred section, of which the well-known *Aquilegia chrysantha* may be regarded as typical, and which, when well established and covered with its myriads of blossoms, may take a place among the best choice perennials. These *Aquilegias* are easy to cultivate, and their best method of propagation is by seeds, which they yield abundantly, and there is ample scope for those endowed with patience to improve the existing forms of these flowers. In the flower garden, where partial change is needed from the general run of bedding plants, these *Columbines* are specially adapted; and, growing well in ordinary vegetable soil, is only another point in their favour. They make a most pleasing bed alone, or they may with good effect be associated with annuals in the mixed border, or with some dwarfed bedding plants. I remember a charming bed in a lady's garden in the vicinity of Bath. It was in full flower at the time of my visit, and despite the gaiety of the other beds near by I found greater pleasure in these *Columbines* (hybrids of *A. californica*) than in all the gaudy colours of the Zonal *Pelargoniums*.

It is not wise, perhaps, to speak in high praise of any group of hardy perennials however meritorious they may be, and their introduction into the flower garden generally, without attempting to show how they may be employed so as to harmonise with other plants around them. For example, in the genus of which I speak, the earliest of its members do not commence flowering till the middle of June, depending in some measure on the season itself, so that we could hardly be content that these should occupy permanent positions in the flower garden, and so long without flowers. In such a case as this, however, there is ample room for introducing a few of the many spring bedding plants planted indiscriminately amidst the glaucous tufts of the *Columbines*. Such as these would make the bed gay ere the *Columbines* expanded, and when these began to wane the *Columbines* would be ready to take their place, and by planting a few white Tobacco (*Nicotiana affinis*) if space permitted a good bed may be made for the rest of the year. Many more examples might be given, but one will suffice, seeing that the plants available for making pleasing combinations in such beds are numerous, and most occupiers of gardens design such beds to meet their especial circumstances and tastes.

It may not be altogether lost if I briefly cite some of the most showy members of the *Columbine* family, and by giving to each its average height and predominant colour, may tend to assist those desirous of embracing one of the most elegant groups of perennials.

**A. ALPINA.**—This is a showy species, growing from 1½ foot to 2 feet high and bearing showy blue flowers; a most desirable plant for the second row in the border or for the higher positions on the rockery. It succeeds well in ordinary sandy loam of good depth made fairly rich, and where possible comparatively moist. It inhabits high elevations in the European Alps, over which it is somewhat widely distributed. This must not be confounded with *A. vulgaris*, flowers of which are of a deeper purple-blue, though the characteristic distinction is in its longer stamens and larger flowers.

**A. CÆRULEA** (The Rocky Mountain *Columbine*).—Here we have one of the choicest alpine, and one which cannot be too highly recommended. Among hardy-plant growers it is well known, and its unique beauty warmly appreciated. It grows freely in any warm sandy soil (here in passing I may remark that the *Columbines* as a whole object to stiff or cold soils), and grows about 18 inches high; the foliage assumes a deep glaucous hue, and is much divided. From the bushy rootstock arise the somewhat branching flower stems, on which are situate numbers of its lovely blue-and-white flowers. These are erect, and display the flowers to advantage, a combination so charming in the soft blue of the sepals and pure white petals that it has been compared to "a large soft-coloured Clematis," and while I cannot discover the slightest resemblance, it must be regarded by all as one of the handsomest perennials. It flowers in early summer, and lasts a long time in perfection. By saving a few seeds each year and sowing early in January an annual display of this charming plant may be guaranteed, and as I rest in the full belief that no one having once succeeded with it would care to be without it in future, it is worthy any care or extra attention to keep up a good supply. It is worthy of remark, however, that it is of easy culture as compared with some of the other rare species—a point considerably in its favour.

**A. CALIFORNICA.**—A most distinct and highly decorative species from the locality signified in its specific name, and which has, in conjunction with the yellow-flowered *chrysantha*, produced some chaste and elegant hybrids. It attains a height of 2½ feet, and produces flowers of a bright scarlet hue somewhat profusely. If only on account of its distinguishing colour, it is entitled to a first place among choice hardy plants. When established it forms a compact handsome hush.

**A. CHRYSANTHA.**—One of the most showy and floriferous of all the *Columbines*, and one which when well established in a deep rich

soil (which, by the way, all the taller kinds enjoy) attains a height of some 3 feet and nearly as much in diameter. It is at this stage which under good cultivation may be reached in about three seasons that they are admired by all who see them. There is no formality about them, but a natural grace and beauty which all may enjoy owing to their delicate and pleasing shades of colour. It is by letting them alone after being once well planted that they may be had in perfection. It is not uncommon for this species to continue flowering for two or three months, and taking into consideration how charmingly its light golden flowers mingle with other shades of colour it at once stands forth as a valuable plant either in a cut state or for border decoration. I would not advise the planting of this species in shrubberies, for in almost every case it is sure to become crowded by stronger growers. Rather give it a good position in the open border or bed—a central one if possible, where it will have ample room for free development. This species is better known than many, and is quite distinct from any other of this genus.

**A. GLANDULOSA.**—This is not only one of the most lovely species of this genus, but it is at the same time one of the most exquisite of hardy perennials. No greater praise can be accorded it than this, and this is not more than it deserves; and the large handsome flowers, the sepals of which are of a deep rich blue, with pure white corolla, making it one of the most desirable plants for the rockery or for the front row in the border. It grows from 6 to 10 inches high, and should be planted on slightly elevated positions on an even surface. Anywhere in flower it is one of the most conspicuous of the alpine section, and inhabits the Altai Mountains. If disposed in small colonies on level surfaces of the rockery, where a good depth of sandy soil mingled with stones to keep it uniformly moist at the roots can be given it, it will be found to thrive admirably. It deserves every attention and well repays good cultivation.

**A. LEPTOCERAS LUTEA.**—A rather pale yellow-flowering variety, with habit similar to *A. chrysantha*, though not so tall or showy as that species. The spurs are much shorter and not so much recurved. It seldom grows more than 2 feet high, of sturdy habit, and rather free-flowering.

**A. PYRENAICA.**—A very pleasing *Columbine* of dwarf habit and pale violet flowers, best treated perhaps as a biennial to insure a continuance of its flowers annually. It produces seed freely, and these vegetate quickly if sown as soon as ripe. It grows about 10 inches high, and should be included among the choice occupants of the rock garden.

**A. SKINNERI.**—In point of colour we have another very distinct species, the flowers being of an orange-red and slightly tipped with green at the mouth. It grows nearly or quite 3 feet high, though not so bushy or compact as some, but still very interesting and distinct; and then, apart from those above named, we find some useful plants in the forms of *vulgaris*, both single and double. In the latter we have its double white form, which is very useful in a cut state. *A. vulgaris caryophylloides* is also a double, and whose flowers are handsomely striped. *Witmaniana* has flowers of blue, violet, and white, and is a good useful border plant; while in *atrata* we have one of a vigorous constitution and deep reddish violet flowers. The foregoing are among the best of this very pleasing and free-flowering genus of hardy plants. There are, however, many more both of species and forms, and new varieties are continually coming in view. One of these, *grandiflora alba*, is a fine new white with single flowers, good robust habit, 2 feet high, and a welcome addition to the list of good things. In conclusion, I may remark that a wide field is open for improvement among these plants, and their free-seeding qualities and perfect hardiness are points in their character, with easy culture, that cannot do other than make them popular subjects, embracing as they do a flowering period of about four months.—J. H. E.

#### GARDENERS AND PREMIUMS.

I HAVE been reading the contributions on the above subject with great interest. First of all I cannot see why a premium should not be paid by an apprentice in our profession just the same as by an apprentice in any other trade and profession. In most cases there is no distinction made between the young man that paid his premium and the one that paid no premium, nor should there be, for I think that any young man should be appreciated according to his abilities, whether he paid premium or not. Some young men are more fortunate than others in procuring situations in first-class establishments where no premiums are demanded, but there are in most first-class establishments some young men that have paid premiums and some that have not; therefore, it is interesting to hear the different opinions on the subject.

Some years ago I applied for a situation as improver in a noted earl's garden in one of the Midland counties, and received a reply to the effect that £10 was required as a premium. Being very young at that time—viz., seventeen years of age—I had not much money, but I overcame the difficulty by obtaining a friend who was kind enough to advance me the money, on the agreement that I should return it in small payments

monthly, as I could afford it. This I did, and the debt has been repaid some years. In due time I arrived at my situation and found the head gardener a very firm and strict but kind man, just the sort of master any young man should be under. At first I was set to work with the outside foreman until there was a vacancy for me in the houses. As I was a strong lad I set to work with a firm determination to do my duty to the best of my abilities, also to obey both my master and his foreman's orders. Accordingly I began to succeed, and the head gardener took an interest in my welfare and was kind to me; but, as I have said before, was very strict, and, to tell the truth, I sometimes used to think he was far too strict, but I have found out since that it was all for my good.

After working with the outside foreman for two months I was removed into the houses under the foreman there. For ten months I was constantly working with the foreman in all the different departments. When a vacancy occurred in the fruit houses I was put in charge of them, and at the same time the head gardener was taking great interest in me, for he was constantly advising me to keep a diary and to take notes of all outside work that was proceeding. I am now thankful that I took his advice and did so, for in the position I occupy at present I find it greatly to my advantage to be able to refer back some years on different subjects. The head gardener kindly gave me a box of drawing instruments and a book on geometry, so that I could practise drawing plans in the winter evenings. I cannot speak too highly of him, for his conduct towards me was that of an honourable but very firm master; and such it is to every young man that is under him if he tries to do his duty.

After living with him for nearly three years I thought I should like a change, and of course spoke to him about it. He said he would get me another situation if I wished to leave, but I need not leave unless I liked. He obtained a situation as journeyman for me in a first-class establishment, in which I was over three years; therefore, I do not regret in the least having paid my premium.

But perhaps "W. P. R.'s" friend, and some more of your correspondents' friends, were not so fortunate as I was in being apprenticed under a good master. There is, however, no doubt great annoyance to a head gardener when he has some young men to deal with that ignore the foreman's authority, and will not turn out with the other men. I have seen some of the most ignorant fellows that ever entered a garden, who thought that because they had paid a premium they were above the other men, and were not supposed to work, but simply look on and walk about with their hands in their pockets. I have also seen more cases than one where such men have ignored the foreman's authority, and would laugh at him when he corrected them or found fault with their work. I have also seen cases where such men would not turn out with the others, both in the morning and after meals, and have often had to be reprimanded by the head gardener; therefore, had I been "The Earl's Gardener," and had such a young man to deal with, I should have acted precisely as he did, and would discharge any man that did not try to do his duty. But as I am not a head gardener I content myself at present with bolding the title of (in an earl's garden)—AN OUTSIDE FOREMAN.

I HAVE read the "Earl's Gardener's" version of the case, which has aroused this correspondence, and am willing to give it respectful consideration. Your correspondent asserts that the "£5 was to be paid down." The young man, on the contrary, says that in the letter stating terms not a word was said respecting the mode or date of payment, and as your correspondent "Another Observer" seems to have interviewed him, I have requested that the letter should be handed over to him.

Contradictions may be expected in this like many other cases, and the truth of some of the statements can only be known to the parties concerned. There are others, however, whose circumstantial evidence we may fairly discuss, and I venture to question the truth of the allegation the young man was incompetent, or, in the words of the principal foreman, as quoted by "Observer," "he was no use at his work," and, as the gardener states, "work that he was engaged for—viz., assisting the foreman furnishing, and filling his time in the houses." Now, I ask, is it reasonable to suppose that a young man brought up in the florist's business with his father, who grows plants, also undertakes furnishing, as well as spending two years in a public pleasure garden where similar work was conducted, could he so helpless as to be of "no good at such work?" I may state that the young man was introduced to me as one requiring a situation, and as there was a vacancy about to take place in this garden, I naturally asked where he had lived and for how long, and why he left. The substance of the replies was given in my first letter, but whether I acted right in making it public instead of making private inquiries, as hinted by "Observer," is really a matter of opinion. Some one has said that "a lie will run round the world before truth puts its boots on," and it might be added that there is nothing like publicity to arrest its progress. If I have effected that object by giving the "Earl's Gardener" an opportunity of making a public denial of the allegations made against him I claim to have done him useful service.

Judging from the young man's appearance I should have had no hesitation in engaging him for a post of 18s. per week and bethy, but the following morning satisfactory replies came respecting one I had communicated with already. I observed the ring, but it made no impression on me. It was a plain article, such as I have frequently seen navvies wear. His early surroundings will account for his personal attire. Like "A Gardener to an Earl" (see page 397), I have no objection to gardeners receiving premiums, provided they give reasonable value in return, as was the case in the gardens that I once served in. The gardener was well educated, and the more the young men sought his assistance with their arithmetic, grammar, drawing, and naming wild

flowers the better pleased he was. This is quite different, as the same correspondent remarks to a young man paying "for the bare privilege of working in the garden." I, like the same correspondent, have received liberal overtures in the premium line, and am at liberty to accept them, but have not thought fit to do so. If I did I should not ask for payment beforehand.

Since writing the above I have received written testimony from a lady as to the young man's ability and taste in furnishing her place when engaged with his father. Whilst in the same service he arranged a group of plants for effect at one of your suburban shows and gained a prize. He also made a bouquet for the same show, and won second prize out of forty competitors. This was selected by one of our Royal Princesses, and the secretary had to seek the maker in order that he might present it to Her Royal Highness. This is the man your readers are asked to believe was "no good at his work."—W. P. R.

[We have received a letter from "Another Observer" quite too late for publication; he, moreover, goes over exactly the same ground as "W. P. R." does, but further states that there is no mention in either a letter or on a post card in his possession from the Earl's gardener to his late pupil relating to either the time or the manner that the former expected the premium to be paid. It appears to us that differences of opinion must of necessity prevail on this particular case, however lengthened may be the discussion thereon. Granting a young man's talents as a decorator and bouquetist, very different work would be required of him in a large private garden; moreover, however able an under gardener may be, he will fail if he ignores the foreman's authority and does not keep proper time. The case having been stated and answered, future communications should pertain to premiums generally, which is a proper subject for public discussion.]

## HELIOTROPES FOR WINTER.

THE fragrant flowers of the Heliotrope—like the Mignonette, are always welcome whenever they can be had, especially during the winter and spring months. It is by no means difficult to grow and prepare the plants for flowering from the end of October until flowers can be gathered outside in July. But the greatest difficulty experienced in many gardens is a suitable structure in which to accommodate the plants during that period. They will not flower under greenhouse or comparatively cool treatment; but to maintain growth and a supply of flowers in succession a temperature of 55° to 60° is required. A supply can be maintained during the months of November and December in an average temperature of 50°, but the plants will fail to flower again until the middle of February, when the days have lengthened and the external atmosphere is becoming warm.

To attain success in the culture of these plants in pots they should be propagated annually. Plants raised from cuttings the same season always flower with greater freedom than old plants. It is a general practice in many gardening establishments to retain standard and pyramidal plants year after year for producing the supply of flowers during the winter and spring. This system is a mistake, for old plants become woody, and in consequence do not grow with the same vigour as young plants. The growth of old plants when confined in pots is very frequently weak, and it ceases quickly during dark sunless weather. To have an unbroken succession of bloom the plants prepared for the purpose must be kept slowly growing the whole time and then flowers are certain, but directly growth is brought to a standstill either by too low a temperature or from any other cause the plants at once fail to flower.

Standard, as well as pyramidal-trained plants, are very effective during the winter when associated with other flowering plants. It is a matter of taste whether these be trained upon wire trellises or not. For our part we do not care for closely trained specimens. Some, however, admire trained plants, and in such cases the ordinary standard trellis provided for Mignonette is not large enough. The size of trellis most suitable depends entirely upon the taste of cultivators. A very serviceable size for standards are those with stems 3 feet in length, and circular heads about 2 feet 6 inches through. A good size for the latter is the same distance at the base as required for the head of the standard, with a central stake about 3 feet high. Pyramidal trellises are easily made by stretching a few wires across the central stake and securing them to the ring at the base, or they may be formed by the means of a few stakes only.

Young plants, which will now be well established, must be potted from time to time as they fill their pots with roots, until they are placed into 10 to 12-inch according to the size of the plants required. They should not be stopped till the stems reach the height desired, and side shoots from the axils of the leaves should be removed. The plants should be first grown in heat, but the temperature should be gradually lowered so that the plants can be grown on under greenhouse treatment from the time they are well established in their largest pots. After

stopping, those plants that are to be trained on standards should be allowed to develop a certain number of shoots until they are sufficiently long to reach the outside of the trellis, when pinching and training should commence. Those intended to form natural heads without the aid of a trellis should be pinched from time to time as a few inches of growth has been made, so that a close compact head will be formed.

Pyramids can be grown from a single plant by pinching the leader as it extends upwards to cause the formation of branches to furnish the base. This takes a much longer time to furnish the trellis thoroughly than when four plants as soon as they are rooted are placed together into a 4-inch pot. The centre plant should be trained upright, and the other three outwards until they are sufficiently long to reach the outside of the trellis; but this will not be the case until they are placed into their largest pots. These should then be pinched, and the central plant about three times before it reaches the limit of the trellis. This is important in order to furnish the base of the trellis, for if this can be accomplished there is no difficulty in covering the upper portion.

Standards and pyramids when trained upon trellises take a longer time to cover them than those having no trellis do to form a good head, therefore they must be grown under glass for fully a month or six weeks, probably more, longer than the others. When the head has commenced forming, and the weather is genial, the plants should be carefully hardened, and then grown on outside for the remainder of the summer. Care must be taken that the plants when turned out are not checked and growth brought to a standstill, or they will fail to make the progress desired to form good heads. The trained plants, when it is certain that the trellises will be well filled with wood, may also be grown outside.

When outside the pots should be plunged if practicable to shelter them from the sun's rays, and to prevent them being dried too rapidly. While outside expose the heads of the plants to full light and sunshine, which will result in the formation of short sturdy well-ripened growth that will be certain to flower well. Do not pinch those plants intended to commence flowering about the end of October after the last week in August. To have good plants with their heads well furnished by that time it is important that an early start be made.

Beautiful plants can also be grown in 5 and 6-inch pots for furnishing rooms or associating with other flowering plants in the conservatory or any other structure where the desired temperature can be maintained. For this purpose root cuttings during May, and transfer them into 3-inch pots when ready. The point of the young plants should be removed as soon as they are established in the small pots, and this practice must be continued until the end of August. By the time the small pots are full of roots the plants will be bushy little specimens with four or five shoots, and be thoroughly hardened ready for turning out of doors by the time they are placed into their largest pots. Press the soil firmly into the pots to insure sturdy growth, and plunge them in an open sunny position. If these plants are well attended to as regards pinching the shoots they will be handsome bushy plants with six to twelve shoots.

While growing *Heliotropes* must never be allowed to suffer by an insufficient supply of water at their roots; in fact in no stage of development should they be allowed to become dust dry. If they are watered carelessly and allowed to get into this condition during the season of growth the wood becomes firm, and they fail to make satisfactory progress. As soon as the plants, whether standards, pyramids, bushes, or small decorative plants in 5 and 6-inch pots, have filled their pots with roots supply weak stimulants every time they need water. Soot water is very beneficial for them, and might with advantage be applied alternately with liquid made from cow manure. Perhaps the safest and easiest method of feeding is to apply a little artificial manure to the surface of the soil about once a fortnight. The large pots during bright dry weather may be mulched with a little short manure.

The plants must be placed in their winter quarters by the end of September, for one cold night or slight frost will ruin them. It is not necessary to give them heat when they are first housed; on the contrary, a cool light airy position is most suitable for them at first. The only care needed while the plants are in a cool house is that the temperature does not fall below 50° at night, or they will be seriously checked. Very little trouble will be needed to maintain this temperature during the following month, and very little artificial heat will be needed in order to do so. The first plants can be brought into flower without fire heat, except on solitary occasions, if the ventilators are kept close, and every advantage taken of sunny days. At that period

of the year if no air is admitted to the plants they will take no harm, for the power of the sun is not sufficiently strong to scorch or injure them. They can be grown and flowered successfully without ventilation. Sufficient air for their well-being during the dreary days of winter finds its way into the house through the doors and laps of glass in the roof. I find no variety better for winter than *White Lady*.—W. B.

## THE INSECT ENEMIES OF OUR GARDEN CROPS

### THE APPLE.

(Continued from page 276.)

A THOUGHTFUL schoolboy, meditating upon the economy of the codlin moth (*Carpocapsa pomonana*, fig. 75), might say to himself, How wise and kind has Dame Nature proved to be in this instance, by thus providing for young folks an abundance of windfalls. Not, indeed, that all the fruit brought down by the summer gales has suffered from this pest, but no doubt it is the cause of the descent of multitudes of Apples and some Pears. Often is the fact that the fruit contains a lively tenant scarcely noticed by the eater, who helps to reduce in this way the number of next season's insects. Named from the Codlin, it is a species really not particular about the sort of Apple, but rather prefers that to the Pear, the moth pursuing the same plan with both, by placing one egg in each fruit visited, generally upon the eye. The emergence from its pupal stage, in which this insect winters, occurs during May, early should the spring be mild. As I have previously remarked in these pages, smouldering fires of weeds have been tried with a view to stop the deposition of eggs by

Fig. 75.—Codlin moth and larva (*Carpocapsa pomonana*).

this and other spring moths, but they only give a slight check, the smoke cannot be effectively concentrated upon trees. Slightly magnified the moth is seen to be a pretty species, pale brown, lined in darker tints, and having on the fore wings a patch of reddish gold with a lighter border and hind wings shading from brown to black.

When first hatched the caterpillar of the codlin moth is white, having a black head; it gets rather darker as it grows to the length of half an inch in five or six weeks. Instinctively it avoids touching the core of the fruit for a time, which would send it too speedily to the ground, but passing beside the core works a gallery to the surface; from the orifice of this it can eject what the Germans call its "frass." Then it glides back to the interior, and before the Apple is ripe its enemy, by biting through the centre to eat the pips, occasions its fall and quits speedily as a rule. An effect of the attack of this insect is to hasten the development of sugar in the fruit, so that a windfall would be found nearer ripeness than a sound one picked from the tree. Rather singular is the next move. The caterpillar travels off to some tree or paling, seeking a crevice under bark, where, having hidden in a web, it becomes a chrysalis. With us the insect is now quiescent until the following season. I have no satisfactory evidence that there is a second brood in Britain, but I believe the appearance of part of the spring flight of moths is occasionally delayed, so that there is a succession on the wing. Abroad—that is, on the Continent, the change is speedier, the caterpillars growing rapidly turn to moths in the summer, and these deposit eggs of a second brood on fruit that had previously escaped.

Common sense suggests the prompt removal of windfalls, whether to be eaten or destroyed. It has even been advised, should the wind have left the trees undisturbed, to shake the trees well where this pest has been abundant. Those who are careful to dress both trunks and branches at the suitable time,

obviously kill or remove various insects, and also leave fewer lurking places for others, as in this case. Contrivances have been resorted to which might prevent the caterpillars that have left fruit reaching any refuge, and then crawling about they are likely to be picked off the ground by some insect-eater. Not many fruit-growers, however, seem to think it needful to take such precautions, though perhaps they err in not so doing. Thus, a tarred band round a trunk would stop their approach to it, or a circlet of sand damped with paraffin prove too odorous for them; and such a simple application as a layer of softsoap, over which scarcely a caterpillar, large or small, will crawl if it can be avoided, will be useful, only this is washed away by heavy rain. From standards or young trees any fruit that shows the presence of this insect should be picked off at once.

The extensive and abundant family of the sawflies contains species that rank with the worst enemies of the garden and orchard, some by their ravages committed on leaves and fruits, others by their attacks upon the growing wood of saplings or trees. From the curious resemblance that many of the larvæ or grubs have to those of the moth tribe, they have been called pseudo-caterpillars, but when feeding externally they have a method of swinging their bodies in the air, which is not practised by the larvæ of Lepidoptera, also in their number of legs they exceed those. Much as the Apple suffers from the attacks of true caterpillars, it escapes lightly from most of those of sawfly parentage, even more than does the Pear. It is the custom in some orchards or fruit plantations, for instance, to have an undergrowth of Gooseberries and Currants amongst the trees, and there sometimes the leaves will be stripped, especially those of the former, by the bluish green and black grubs of *Nematus ribesii*. However hard pushed they may be for food, they will sooner, I believe, die on their native bush than ascend an Apple tree, or indeed a Plum or Pear. But the Pear, like the Plum and the Cherry, is victimised by the insidious slimy grubs of *Selandria cerasi* or *pyri* (it appears that we have several species nearly allied and scarcely isolated as yet), these not merely devouring the whole upper surface of many leaves, but injuring the tree by the pernicious character of the substance they exude. Since slugworms, as these sawfly grubs are aptly called, are also found on Hawthorn and Sallow, I see no reason why they should not infest the Apple, but so far they have not been reported, nor have I observed them.

The chief foe to the Apple of the sawfly tribe, but one not excessively abundant as a rule, is *Tenthredo testudinea*. Prof. Westwood seems to have been the earliest to chronicle its occurrence. "At the end of June, 1838," wrote he, "I observed that nearly the whole crop of young Apples in the garden of my residence at Hammersmith had fallen to the ground, being then about the size of small Walnuts, and on opening some of them I found the interior devoured by the larva of a nematus having twenty feet, and a body thickly wrinkled. When alarmed, they emitted an odour like that of the *C. lectularius* or bed bug." This last circumstance is peculiar, because an offensive smell amongst insects is generally given as a means of defence, and larva, feeding as these do, can be in no danger of being devoured by larger insects or birds. It suggests that the species has possibly changed its mode of life. The fly is particularly timid and difficult to capture as it wings its course among the Apple blossoms during May. Above, the body and legs are shining black, the under surface being orange, the wings are transparent and tinged with brown. From the flower the tiny grub passes into the immature fruit, as described by Westwood, but it does not prolong its stay there, as does the caterpillar of the moth mentioned above. At the end of June or early in July, the fruit being about one-fourth the proper size, it has succeeded in stopping farther growth, and the Apple attacked is therefore dropped by the tree. As the grub is then full-fed it quits its abode and enters the earth, not far beneath which it makes a cocoon, abiding there till the following year. Evidently those measures taken for the destruction of insects generally in the surface soil around fruit trees during the winter season will kill most of the cocoons of this fly. The six-footed semi-gregarious grubs of the sawfly genus *Lyda*, have been stated, on rather doubtful evidence, to feed sometimes on Apple.

Almost fifty years ago an entomologist, not a gardener, detected the caterpillar of a moth mining in the shoots of the current year, and generally causing them to wither up. This species also frequents the Pear, but then prefers the solid wood. From its fly-like aspect, coupled with a red band round the body, the moth is called the red-belted clearwing, and in science *Sesia myopæforme*, rather absurdly, for this insect is by no means a short-sighted creature, which is evidenced by its selection of a place for the caterpillars. These are small, very muscular, and with legs; their whole life being passed in the pith or wood as

the case may be, and they turn to pupæ in the spring, the moth emerging about midsummer.—ENTOMOLOGIST.

### RUSHING INTO PRINT.

"OBSERVER'S" remark to the above effect, in reference to "W. P. R.," page 398, brings a good story to my mind that has the merit of being true, and as there appear to be many anonymous allusions flying about over the premium question there is no harm in relating it; but I leave that to your editorial discretion. The story relates to one the initials of whose name are "W. P. R.," under which signature he has at times written to the horticultural papers, although I do not wish to convey that your "W. P. R." and mine are one and the same person. They may be totally different persons for anything I know, and probably are; but be that as it may, the "W. P. R." I speak of was, a good many years ago, foreman at a place I know particularly well, and on one occasion while there he sent a graphic account to one of the gardening papers of an extraordinary crop of a certain useful and acceptable esculent produced under his charge, signing his name or initials, I forget which now, and giving the name of the place. This he did without the knowledge of his master the head gardener, who did not see the paper in question. Unfortunately, the crop of — that year up to that time had been a failure so far as a supply to the kitchen was concerned, and it so happened that some acquaintance of the employer (who is a nobleman) drew the latter's attention to the paragraph about the remarkable crop of — in his garden as reported. Judge, therefore, of the head gardener's confusion when one day soon after his employer came into the garden, and drawing the paper containing the report from his pocket, observed good-naturedly, "D., I would like to have some of these fine — myself!" The reply of the gardener was, "And you should have had, my lord, if the story had been true; but I never heard of it till this moment." It was the foreman's turn next, and one of the principals in the matter who told me said, "he believed he had a bad quarter of an hour." He did not "rush into print" any more while there; but he did after he left some time, and his gross exaggerations had to be reported to the editor of the paper by the then head gardener of the place. They related to a crop of another kind at the same place—and of course grown when he was there—but which had no existence in reality.—HEAD GARDENER.

### ORANGE CULTURE IN FLORIDA.

(Continued from page 379.)

**THE AGE OF THE ORANGE TREE.**—The great age to which the Orange tree lives and bears is an important consideration for the colonist, who might, by a little self-denial, and through a judicious first selection and expenditure upon an Orange grove, virtually endow his posterity with an annually increasing income. Risso, in discussing this matter, mentions that, in the convent of St. Sabina, at Rome, there is an Orange tree said to be 600 years old, and at Nice, 1789, there was another which usually bore between 5000 and 6000 Oranges; its trunk took two men to encircle it, its crown was more than 50 feet from the ground, and its age was lost in antiquity. Even in England, Orange-rearing, during a considerable part of the year in the open air, has not been attended with much difficulty, as witness the Baddington orchard in Surrey, of which Bishop Gibson, in his contributions to Camden's "Britannia," says it "was 100 years old in 1695," the Hampton Court Orange trees, some of which are stated to be more than 300 years old; and various gardens in South Devonshire, where, trained against the walls, and only protected with straw mats during winter, are specimens which have flourished for at least a century.

**LARGE ORANGE TREES.**—The following are a few of the large Orange trees in Florida:—The Fort Harley tree, in Alachua County, supposed to be seventy-two years old, which has borne 18,000 Oranges in one season; another in St. John's County yields 15,000; another in Bradford County over 10,000; and a Lemon tree, at Fort Reid, thirty-two years old, has borne over 20,000 Lemons. These are only a few of the large Orange and Lemon trees in Florida.

**MARKETING THE ORANGE CROP.**—Nothing but the superior quality of the Florida Orange has saved it from extinction in the market. It is sad to ponder the losses that have been the result of such gross mismanagement. Many a poor young man, after five or ten years of unremitting toil, had brought his thrifty trees into bearing, and confidently consigned them, duly packed and labelled, to the far-off unknown commission man in New York, Philadelphia, or Chicago. After weeks and months of weary waiting would come a cheque of such a small amount that the grower, eagerly looking over the accompanying letter for the reason, would read: "Your fruit came to hand on the 22nd in bad condition, being two weeks on the road; much was badly frozen, and quickly decayed, &c." Or instead of cheque, perhaps came a letter similar to the above, enclosing a bill for transportation for the fruit that was ruined by the company's neglect. Other fine Oranges, well packed, arrived in good order, and straightway fell into the hands of a "bogus" or "curbstone" merchant, who pocketed the receipts *in toto*, letting the far-off unsophisticated grower whistle for his money. Representatives of the latter class annually make winter trips to Florida, spend their ill-gotten gains in high living at the grand hotels, scatter glittering stencil plates and glowing circulars among the Orange growers soliciting their custom, and depart, like trappers, to await the result after setting their snares. As the fruit began to colour on the trees, the owner would ask his neighbour who he was going to ship his fruit to. The answer would be, "I reckon

I will try S. this year, C. cheated me so last. He talked so fair I could hardly refuse him." No. 1 would answer, "Well, if you trust him I will too." In like manner nearly the whole crop of the neighbourhood would perhaps go to one rascal, and an otherwise thriving community be seriously embarrassed.

This has been the darkest side of fruit-growing in Florida, with exceptions more or less for the better, as the honesty of the dealer and the efficiency of the transportation company were apparent. Last winter the situation became so serious that public meetings were held, and each local paper devoted columns to this important question. The result has been that a "State Fruit Exchange" has been formed, with headquarters at Jacksonville, Florida, incorporated under the excellent State laws, whose stockholders embrace many of the largest Orange growers, none of whom can own but a limited amount of stock. This company has already secured a warehouse and offices in Jacksonville, and its general manager has established agencies among the most prominent and trustworthy firms in each of the large northern cities. The abuses as detailed above, it would seem, are over; so the greatest dread of the settler bids fair to vanish, for the advantages of such a co-operative systematic action are apparent. The Florida Fruit Exchange proposes, with all its advantages, to handle all fruit consigned to it, and remit for the same weekly. Its manager will be in constant telegraphic communication with the great markets, and the law of supply and demand can thus be acceded to, and the gluts that sometimes occur in one city while another is not supplied, can be remedied.

While we do not look for perfection the first year in this untried enterprise, it is yet a step in the right direction, and the noble Florida Orange will be enabled to occupy the position and command the price which its rare qualities entitle it to.

### ROYAL METEOROLOGICAL SOCIETY.

THE usual monthly meeting of this Society was held on Wednesday evening, the 19th inst., at the Institution of Civil Engineers; Mr. W. Ellis, F.R.A.S., President, in the chair. Mr. L. T. Cave and Rev. C. Malden, M.A., were elected Fellows of the Society.

The following papers were read:—1, "The Severe Weather of the Past Winter, 1885-6," by Mr. C. Harding, F.R.Met.Soc. The author showed that the whole winter was one of exceptional cold, not so much on account of any extremely low temperatures experienced, but more from the long period of frost and the persistency with which low temperature continued. In the south-west of England there was not a single week from the commencement of October to March 21st in which the temperature did not fall to the freezing point. In many parts of the British islands frost occurred in the shade on upwards of sixty nights between the beginning of January and middle of March, and during the long frost which commenced in the middle of February and continued until March 17th, the temperature fell below the freezing point in many places on more than thirty consecutive nights. At Great Berkhamsted in Hertfordshire frost occurred on the grass on seventy-three consecutive nights, from January 5th to March 18th. The winter of 1885-86 was the only one in which there was skating on the water of the London Skating Club in Regent's Park in each of the four months, December to March, since the formation of the Club in 1830, and there are but four records of skating in March during the fifty-six years, and none so long as in the present year. With regard to the temperature of the water of the Thames at Deptford, it was shown that the total range from January 8th to March 20th was only 6°, whilst from March 1st to 19th the highest temperature was 36.5°, and the lowest 35°. The temperature of the soil at the depth of 1 foot was generally only about 2° in excess of the air over the whole of England, and from March 1st to 17th the earth was colder than usual by amounts varying from 6.3° at Lowestoft, to 8.5° at Norwood. The facts brought together showed that the recent winter was one of the longest experienced for many years, and that in numerous ways it may be characterised as most severe.

2, "Description of an Altazimuth Anemometer for Recording the Vertical Angle as well as the Horizontal Direction and Force of the Wind," by Mr. L. M. Casella. The author describes an anemometer he has made which records continuously on one sheet the pressure, direction, and inclination of the wind.

3, "Earth Temperatures, 1881-1885," by Mr. W. Marriott, F.R.Met.Soc. This is a discussion of the observations of the temperature of the soil at various depths below the surface, which have been regularly made at 9 A.M. at several of the stations of the Royal Meteorological Society during the past five years. The results show that the temperature of the soil at 1 foot at nearly all the stations in the winter months is almost the same as that of the air, while in the other months of the year the temperature of the soil is higher than that of the air at all except that of the London stations.

4, "Note on the After Glows of 1883-1884," by Mr. A. W. Clayden, M.A., F.R.Met.Soc. The author suggests that the after-glows were the result of the vapour erupted from Krakatau, and that the dust and other ejecta played but a secondary part in the production of the phenomena.

### PROPOSED STRAWBERRY ELECTION.

YOU have held elections of several kinds, and a very great guidance they undoubtedly have been. May I suggest, as the time is now approaching when many will be making fresh plantations, that a Strawberry election would be exceedingly useful, especially if the electors would state the county they live in, their soil, and the sorts they grow.

From the multitudinous sorts advertised in catalogues it is very difficult to make a selection, and it generally happens that on reference to neighbours the answer is either "I don't know what sort it is, but those I have got are very good," very likely that being the only sort he knows anything about, or "You should get Keens' Seeding, Sir J. Paxton, or some other of the widespread well-known sorts." Hoping that you may favourably consider this suggestion.—J. E.

[There was an election of Strawberries a few years ago obligingly conducted by Rev. C. P. Peach, who acted as the returning officer, and the results were published in the *Journal of Horticulture*. It would be useful if growers of several varieties were to give a selection of those they find best for insuring a supply of fruit from the earliest to the latest period of the year, also the most productive and useful varieties for market and preserving. It is obvious, however, that the positions the plants occupy have an important influence on the duration of the Strawberry season, early varieties on warm borders and late sorts on northern aspects accelerating and retarding the ripening of the fruit. We will readily publish lists, with hints on management on the lines indicated, that may be sent to us by cultivators. If more than twelve varieties are named it would be useful to append a mark against the best six for succession, and the best three for market; also to state the nature of the soil, as strong, medium, or light in texture.]

### VIOLETS.

(Continued from page 376.)

THERE are places in every garden devoted to the commoner flowers where they often afford an agreeable surprise. Violets are spoiled by petting, which only makes the plant gross, sparse-flowering, and tender. Sturdily reared and properly tended plants only are hardy and floriferous. Shrubby horders, the space in front or between, not under shrubs, or where the ground is preoccupied by their roots, kept free of weeds, and pointed over once a year with an occasional surface dressing of leaf soil, the *débris* of the rubbish heap, or well-decayed manure. Odd corners about the grounds, some in the sun, others in the shade. Borders at the side of walks—anywhere except beneath trees that so occupy the ground with their roots as to convert it into a barren and dry land in summer. Eligible places are found alongside of Gooseberry or other bush fruit in the borders of kitchen gardens where the Violet plants have the benefit of hushes' shade and shelter without being overhung. The most suitable places are those where there is slight shade from summer sun, as east, west and north borders with shrubs at the back, full exposure overhead in winter, but with screening plants, shrubs, fences, or low walls near, and with a view to late blooms north borders permanently shaded.

Dry places, whether beneath trees, rubble and gravel, shallow soils, hot and dry, in which the plants are likely to be sunburnt, and wet places in which water stands for any length of time after rain are not suitable for Violets. Violet essentials are light, not glare; shade, not gloom; free percolation of water through the soil, not drought; moisture, not water lodging, making the soil sodden and sour; and shelter, shielding from scorching summer sun, and screening from winter's cold.

*Soil and Preparation.*—Violets will grow in almost any kind of soil; good loam, however, is the most suitable, but as the soil of gardens differs according to location it will be necessary in some cases to make additions of other material to render it more suitable. A good friable loam in that happy medium that cannot be classed as heavy or light is everything desired. It will only need turning with a fork a good foot depth. Light soil should have some pulverised clay mixed with it; that is best which has been exposed to the atmosphere some time, so as to have become dried through or subjected to frost, or it should be chopped and mixed with the soil thoroughly to the extent of half if very light, and lesser proportion according to the lightness of the soil. Heavy soil will be improved by the refuse of the potting bench, corks included, burnt clay, brickbats broken small, ashes, and road scrapings. Charred refuse may be used in a moderate proportion, and similar remarks apply to old mortar rubbish. There must be a thorough mixing of the additions with the original soil. One-third or a dressing 4 inches thick may be given of the first named material, and it is better to mix two or more of the materials together, as for instance the refuse of the potting bench and brickbats, or rough ashes and road scrapings, and better still, form as many of the materials named as can be placed into a compost where the soil is very heavy, and in less proportion according to the tenacity of the soil. Alluvial soils may have applications of old mortar rubbish, and peaty soils are the better for lime dressings, and preferably in the old mortar state to fresh. Unless the soil is very poor manure is not advisable. It tends to induce a leafy growth, and the plants are more susceptible of injury from frost. If any manure is given it should be thoroughly decayed. Cow manure is the best for light soil, horse or stable manure is most suitable for heavy soil.

The additions of compost will raise the soil into slight mounds. This is all the better, as Violets like hills, and so far from detracting from the appearance of the borders, is infinitely better than the flat surface so characteristic of the monotonous flower and shrubby border; besides, it allows water to drain away from the collar or necks of the plants. In mixing the added material with the natural soil let it be done thoroughly and a foot deep, forming it into a hillock with flattened top, molehill fashion. Stations for single plants ought not to be less than a foot across, for three plants 2 feet, and for five to seven plants a yard wide. These should be made some time before planting, and the more frequently they are turned in fine dry weather the better the Violet plants will succeed afterwards. If lines are wanted in

borders ridges will take the place of hillocks, and should be 12 to 18 inches wide and rounded at top.

**Plants and Planting.**—The most suitable plants are those taken from outdoor-grown stools. The old stools or plants should be taken up after flowering, or at the close of April or early in May. It will be found that there are plants of two descriptions—viz., runners of last year with more or less roots, and suckers that emanate from the stem of the plant, some, if not all, of which have roots of their own. These two kinds are suitable for immediate planting after being detached or separated from the parent. They should have the runner wire and any large old leaves removed in trimming prior to planting, which will increase the length of the stem of the runner and facilitate the operation, and suckers should be treated similarly in respect of the old leaves; but in each case all the fresh, green, healthy leaves should be carefully preserved, and any straggling or long root stem of the sucker shortened, preserving, however, a good amount of roots to each. Runners are best; the suckers, however, are good, but it is perhaps best to keep each separate—i.e., plant each description by itself. In any case they must be kept as much out of the sun as possible until planted, it being a good plan to lay them as prepared in wet moss up to the collar. Plant the large-leaved or stronger-growing varieties 1 foot apart every way, whether the plants are put three or seven in a group, in threes or sevens, the circles being respectively 1 foot, 2 feet, and 3 feet across, and the arrangement equi-distant. The dwarf varieties will be accommodated with a distance of 9 inches between the plants. The ground should be made firm by treading when the weather is dry. Choose moist weather if possible for planting, and put the plant down so as to leave the centre clear of the soil after it is pressed down about the roots as it should be rather firmly, or as firm as the surrounding ground. Water at once, and through a rose, so as to settle the soil about the roots, which should be repeated each evening until the plants become established, to facilitate which a few branches of evergreens or twigs of deciduous trees in leaf stuck in the ground on the sun side, so as to shade the plants, will be well repaid in the after well-doing of the plants. Keep a sharp look out for slugs late in the evening and early morning, after or before rain. Dust the plants with quicklime late in the evening, which will destroy all it falls upon, and repeat as occasion requires. As a preventive a ring of dry soot may be drawn around each plant.

**After Treatment.**—Weeds should be kept under by running a hoe through the soil frequently, indeed they never ought to get beyond the seedling state. When the plants are growing freely dust with dry soot, selecting a time when the plants are damp, as a dewy morning or late evening. By midsummer, or from then to early July, mulch the soil close up to the centre of the plants and outward to quite 9 inches, covering the ground an inch thick with partially decayed manure, as that of a spent Mushroom bed; moss litter, leaf soil, and cocoa-nut fibre refuse are similarly employed. If the ground is dry a thorough soaking of water should be given prior to mulching. In dry weather give a good watering once a week through the mulching. Runners must be removed as they appear, but it is best to leave a joint or two at the base of each runner in preference to cutting them quite close to the plant. Runners that do not make more than a few inches of wire before showing the tufted leaf growth, the nucleus of the runner plant should be retained and an opening made for it in the mulching, in which it should be placed on the soil and be pegged, or a little of the mulching, or a small stone placed on the wire near the runner, which will facilitate the rooting. In autumn remove any decayed leaves, and stir the surface lightly with a small fork, mulch again with partially decayed manure or other available material, and leave the rest to Nature. In applying the mulch care should be taken not to cover the crowns or bury any of the flower buds. During the prevalence of winds with frost in winter and early spring a few Spruce or other branches around and amongst the clumps or on the sides of rows will afford shelter to the flowers and foliage.

**Second Year.**—After flowering thin out the crowns, leaving the most compact and least elongated, pointing the soil about each plant without much disturbance of the roots. Dress with soot during the first moist weather that prevails afterwards, and mulch with short manure, &c., as in the first year, keeping off all the long runners, and not encouraging any that are likely to cause crowding, it being essential that the plants be kept from becoming a closely matted entangled mass of runners and leaves. Weeds must be kept under, and drought avoided by watering in dry weather. A slight mulch in autumn after clearing off any useless old foliage will be of benefit. Plants so treated will afford a quantity of useful flowers, and by similar treatment will continue to afford them for years; but the flowers are never so large as in the first year, and after the second it is preferable to replant; indeed fresh plantings should be made every year, so that there is a succession of different age.

**Varieties for semi-cultivation:**—

**Section I.**—Plant dwarf and close-growing; foliage and flowers small to medium size; flower stems short to medium length. Suitable for button-hole bouquets, knots for dresses, shoulder and hip sprays, and in small bunches for specimen or finger-glasses in boudoirs, house and table decorations:—

*Viola odorata plena*, double, bluish purple. Spring. Syn. Double Scotch.

— *alba plena*, double, white. Spring. Syn. compacta.

— *elegantissima plena*, double, blue, indigo centre, waxy petals, finely imbricated, lovely, small in all its parts. Spring.

— *rubra*, single, pink. Spring.

— *parmaensis*, semi-double, white striped rose. Spring.

— *Patrie*, double, deep purple-violet, streaked red. September to April.

— *suavis* (Russian, Scotch, London, floribunda, &c.), single, blue. Spring.

— *suavis superba* (Russian Superb), larger in all its parts than Russian; flower blue, rosy purple tinted. Spring.

— *suavis alba*, single, white. Spring. Syn. albiflora.

— *suavis purpurea plena*, double, deep purple. Spring. Syn. Double Russian.

— *suavis alba plena*, double, white. Spring. Syn. Double White Russian.

— *suavis King of Violets*, double, indigo blue. Spring.

**Section II.**—Plant medium and compact-growing; foliage medium size; flowers medium to large; flower stems medium to long. Suitable for similar purpose to Section I. on a larger scale:—

*Viola odorata argenteaflora*, single, white, tinted rosy purple, purple spurs. Spring. If the runners are allowed to remain it flowers most of the year.

— *rubra plena*, double, pink. Spring.

— *suavis La Reine*, double, white tinged purple. Spring.

— *suavis Queen of Violets*, double, tinged purple, flowers occasionally very large. Spring. Syn. Belle de Chatenay. There is a form of this—viz., *cærulea plena*, with double light purple flowers.

— *suavis Devoniensis*, single, purple, sometimes flowers a little in autumn, mostly in spring.

— *suavis Wilsoni*, single purple, white eye, quaint in form, having narrow petals. Spring.

— *suavis Lavisiana*, single, lavender, white eye. Spring.

**Section III.**—Plant strong, foliage large, flowers large, flower stem long. Suitable for large bouquets, vases, &c.:—

*Viola odorata suavis*, Garden vars.:—

*Czar*, single, purple. Autumn, winter, and spring flowering.

*Victoria Regina*, single, purple. Autumn, winter and spring. Raised by Lee.

*Odoratissima*, single, bluish-violet. Spring. Best of the large varieties for outdoors. Raised by Lee.

*White Czar*, single, white. Autumn, winter, and spring.

**Section IV.**—Plant medium; foliage medium large, pointed, and comparatively smooth, shining, light bronzy green; flowers medium to large; flower stems medium to long. More tender than those of the other sections. The most chaste and sweetest of Violets.

*Viola odorata suavis pallida plena*, double, lavender, white eye. Spring. Syn. Neapolitan.

— *pallida alba plena*, double or semi-double, white. Spring. Syn. White Neapolitan, Swanley White, Count Brazzi's White Neapolitan.

— *Marie Louise*, double, lavender blue, white eye. Autumn, winter, and spring.

— *New York*, double, deep mauve, streaked red, white centre. September to April. Syn. *Odorata pendula*, Venice, Marguerite de Savoie, Marie Louise of some, Count Brazzi's Neapolitan.

— *De Parme*, double, deep lavender, white eye. Flowers in autumn, but mainly in spring.

— *Duchess of Edinburgh*, double, cream-white ground, each petal tinted mauve, bordered blue.—**VIOLA.**

THE CHISWICK HORTICULTURAL SOCIETY'S annual Exhibition will take place on Tuesday, July 15th, in the Royal Horticultural Society's Gardens, Chiswick, when prizes will be offered in sixty-four classes, ranging from £5 to 1s., for plants, flowers, fruit, and vegetables. A number of special prizes are contributed by friends of the Society, such as the Duke of Devonshire, Marquis of Bute, Lady George Hamilton, Leopold de Rothschild, Esq., and others. The Hon. Sec. is Mr. J. Fromow, Chiswick.

— MESSRS. ROBERT VEITCH & SON, Exeter, send us some fine flowering branches of *CHOISYA TERNATA* to let us see "how freely it blooms in the open in Devon. The bushes are 4 feet high and 4 to 5 feet through; and after having been in our nursery at Exminster, near Exeter, withstood the severity of the past winter, are now covered with blossom and in rugged health. We do not think its hardiness is sufficiently well known, or it would be oftener met with than it is. Luxuriant growth, handsome foliage, large, Orange-blossom-like flowers, and a delightful perfume place it in the first rank of flowering shrubs." We have seen this handsome shrub out of doors in the neighbourhood of London, but it needs to be grown against a wall, and is then seldom injured by frost.

— "ENTOMOLOGIST" writes—"Recent inquiries about CANER

incline me to the view that probably the truth lies between the arguers. The insect is not the prime agent, as the disease is internal, but, on the other hand, the Acari by their attacks greatly aggravate the injury, and frustrate Nature's efforts to cure."

— A SAMPLE of CALCEOLARIA BLOOMS from Messrs. Kelway and Son, Langport, Somerset, includes some finely shaped flowers, varied in colour, selfs, spotted, and laced. Some have white or very pale yellow grounds, others gold, and still others crimson. All are pretty, and the strain is a good one.

— MR. J. LESLIE of Perth sends us a small bunch of CHRYSANTHEMUM FAIR MAID OF GUERNSEY, which, as he remarks, "though not large, are very late, and there are more to come." The blooms are very fine, and must be useful at this time of year.

— THE BRENTWOOD HORTICULTURAL SOCIETY will hold a summer Exhibition in Weald Park, near Brentwood, in connection with the Essex Agricultural Society's Show on June 17th and 18th this year. Three hundred prizes are offered in eighty classes, the President's prize for a group of Roses, a silver cup value £5, being one of the principal, but the prizes, six stove and greenhouse plants—namely, £6, £4, and £2, are the most valuable offered. The Secretary is Mr. Thomas Haws.

— MR. F. TAYLOR writes from Welbeck on the WEATHER AND BIRDS:—"There were seventy-six martins and ten swallows picked up dead on the 15th inst. close round the Abbey. They had perished through the cold wet weather, besides an immense number on the grounds and lakes. I have not seen a black martin since. There are a few swallows, brown sand martins, and swifts or devlins, as some call them, left."

— THE seventeenth annual Show of the BAGSHOT AND WINDLESHAM SOCIETY will be held in Bagshot Park on June 29th and 30th, a poultry show and rural *fête* being held at the same time. Fifty-two classes are provided for plants, fruits, flowers, and vegetables, the prizes varying in amount from 30s. to 1s. The Hon. Sec. is Mr. W. H. Babbage, Bagshot.

— MR. HARRISON WEIR has succeeded in raising some distinct and beautiful HYBRID PHYLLOCACTI, and flowers of several forms which he had at South Kensington were very brightly coloured. The majority are rich scarlet, but others are more or less tinged with rose, affording very delicate shades.

— THE recent HEAVY STORMS OF RAIN have caused considerable damage in many low districts, much land being under water, and market gardens in the valley of the Thames have suffered severely. Many crops will be greatly injured, and late-sown seed that has not germinated will probably in numerous cases decay in the ground where it is not washed away. Peas have been much damaged in several private gardens, and other vegetables have had their foliage cut by hailstones. Following such a protracted winter, these storms have rendered farming and market gardening prospects still more gloomy.

— MR. BARR sends us flowers of the POET'S NARCISSUS, showing how greatly they vary in size, form, and colouring of the cup. The variations are certainly considerable, and impart additional interest to this favourite flower.

— REPLYING to a correspondent, Mr. Thomas Meehan, Editor of the "American Gardener's Monthly," recently had a note upon the FERTILISATION OF PLANTS which is worthy of reproduction:—"Whether the pistils mature before the stamens (proterogynous) or the stamens before the pistils (proterandrous) is solely a matter of climate or season, and is not a definite character of the plant itself. This, we think, has been proved by the writer of this in the 'Proceedings of the Academy of Natural Sciences of Philadelphia,' though we do not know that the fact has been recognised by European botanists; certainly by none who have written about the fertilisation of flowers. A stamen is excited to growth by a few warm days, while it takes a regularly warm 'spell' to start the pistil. This is the reason why we often fail in getting crops of Hickories, Walnuts, Filberts, and other things when there are a few warm days in winter. The stamens mature long before the pistils push. Hence when they do there is no pollen to fertilise them. In the usual seasons they both push together, or the flowers may be proterogynous. There is no rule for the influence of either parent. The same plant to-day may show a large proportion

leaning toward the male parent. Seeds of the same cross next year may have opposite results."

— AT a meeting of the Royal Botanic Society of London, held on Saturday, Lord Aveland, Vice-president, in the chair, Dr. Cogswell read a paper upon CAMASSIA ESCULENTA, the Camass of the North American Indians, a Liliaceous plant, whose bulbs were once a staple food of the aborigines of the western slope of the Rocky Mountains, though now it has given place in great measure to the white man's corn and vegetables. The season of flowering was held as a high festival by the tribes that assembled together to dig up the bulbs, the maiden who collected the greatest quantity being estimated the most eligible for matrimony. Specimens of the plant in flower from the Society's garden were shown at the meeting.

— A DAILY contemporary observes that the increase of FRUIT PRODUCTION IN CALIFORNIA is remarkable. Last year over 4500 tons of raisins (nearly three times as much as the previous year's produce), 750 tons of Prunes, 910 tons of Apples, 950 tons of Peaches, 570 tons of Plums, 325 tons of Apricots, 625 tons of Walnuts, and 525 tons of Almonds were produced. The yield of honey was 1250 tons. All these quantities are expected to be largely increased this year. Orange-growing is still on the increase, and 1100 car loads of Oranges had been sent out of San Bernardino and Los Angeles Counties by the 1st of April, when the exporting season was not over. As the exporting of Oranges from Florida finishes by about the time when it begins in California, there is really little or no competition between the two States in this branch of industry."

— A CORRESPONDENT of an American paper discourses on the extraordinary fruitfulness of the Strawberry in Florida. The writer, in the presence of witnesses, counted 138 berries, large and small, on a single plant, grown in the open air, in the first week of April. But what is more remarkable than the fruitfulness of the crop at a given time is the unusually long period during which it continues bearing. Last year growers commenced shipping Strawberries to New York and elsewhere on the 9th of February, and continued sending them till the end of May. As late as the third week of June small quantities were picked for local use. More remarkable still is the fact that this prolonged bearing was all from a single variety.

— WE learn that A. H. Smee, Esq., The Grange, Wallington, will throw his garden open to visitors on Saturday next, the 29th inst., when the usual DISPLAY OF ORCHIDS AND OTHER PLANTS will be provided. At this time of year The Grange garden is in its best condition, and large numbers of visitors avail themselves of Mr. Smee's liberality.

— "WILLESDEN" writes, "Will some of your correspondents give me information as to SCHOOL FLOWER SHOWS? What is the best time to hold them? What kind of flowers ought to be grown? Is it best to furnish the plants to the children, or let them buy them? What are the best means to take to avoid fraud, such as buying plants nearly flowered and exhibiting them as their own? I want rules and any information that can be given."

— ANOTHER large shipment of FRUIT FROM SOUTH AUSTRALIA AND NEW SOUTH WALES has reached the market for colonial produce held in connection with the Colonial and Indian Exhibition. It was brought over per the Orient liner "Cuzco," and proved to be in excellent order. The South Australian consignment consists of a selection of Apples, Pears, Oranges, Grapes, Quinces, Almonds, Raisins, Currants, &c. A case of eleven Pears weighed no less than 31½ lbs., five of them being 16½ lbs. They were shown in the South Australian Court on the occasion of the recent visit of the Queen to the Exhibition, and were much admired by Her Majesty, the Prince of Wales, and Princess Beatrice, to whom a basket of the fruit was presented. The shipment from New South Wales comprises twelve cases of various descriptions of Apples and Grapes from the district of Orange, packed on an improved system, which has resulted in a complete success. The clusters of Grapes were perfect. The fruit was exhibited on Tuesday at the Show of the Royal Horticultural Society, after which it was exposed for sale in the Colonial Market at the Exhibition.

#### SPRING-ROOTED HYDRANGEAS.

"G. G., *Hants*," in his remarks, page 408, says striking cuttings of Hydrangeas in the autumn is often attended by disappointment. I advise "G. G.," or anyone else that has not tried, to take the cuttings during

August, selecting strong shoots, and insert them in small pots singly, place them under a handlight or frame in a close warm house till rooted, then remove them to a shelf near the light for a month or six weeks, after which gradually harden them and reduce the supply of water. When the leaves are off any cool shed or pit is good enough for them until they are required to start again, which may be begun in January by bringing them into a gentle heat, in hatches as required to keep up a succession. As soon as they have started growing shift them into 6-inch pots and place on shelf near the glass in a temperature of about 60°. In potting sink them well in the soil up to the first young leaves. Remove suckers or side shoots if any form, and in a short time you will have handsome plants little more than a foot high, with single trusses 18 inches across or more if the best cultural attention is accorded.—FREDK. TAYLOR, *The Shrubby, Welbeck, Worksop, Notts.*

### CHRYSANTHEMUMS—EARLY BUDS.

I WOULD like to ask Mr. Molyneux's advice on a few matters connected with Chrysanthemums, first thanking him, however, for the clear manner in which he is detailing his practice. This is a great boon to many Chrysanthemum growers, and I am following his precepts as closely as I can. I followed him and others very successfully at the shows last year, and hope this year to reduce the distance between us. I hope he will not see a "red light" in that.

My plants now are good, averaging about 16 inches high, and well established in 6-inch pots. Some few of them formed buds a fortnight ago, and others are setting now, chiefly Japanese. I now want to know what is best to do with them. I calculate they will set again in July and early August, but I may be wrong. Would it be best to stop them, say late in May and early in June, according to the variety, whether it is a late or early one, or run them up to the next bud? I think topping weakens a plant, or I should say the break or shoot from a topped plant is not so strong as the shoot from a natural break.

On looking through the plants to-day, May 11th, I find there are more buds formed than I thought or wished. They have been grown quite hard, have never had fire heat. Leaves are large, wood firm, short-jointed, and feathered with leaves to the soil. Everything is right but this bud, which is coming a month earlier than I wished.—CHRYSANTHEMUM.

[I am pleased to find my notes on Chrysanthemums in the Journal have proved useful, but I cannot help thinking that "Chrysanthemum" has not read them so carefully as he ought, or he would not find himself in such a dilemma as he now appears to be in with his plants. However, my wish is to detail my practice as plainly as I can, and I have much pleasure in trying to release your correspondent from his troubles. If he will turn to page 167 he will find what he requires—viz., commencing with the following: "As a general system it is best to allow varieties to assume their natural habits; the growth is then solidified, and all the wants met at the proper time. The plants are not topped at all, but allowed a free uninterrupted growth until the first natural break, which sometimes occurs about the middle of May or early in June, according to the time the cuttings were struck, early or late. When it does occur, the bloom bud must be rubbed out and three of the strongest shoots selected." "Chrysanthemum's" plants appear to have formed the flower bud exactly at the time I indicated. Plants differ in various localities as to the time they show successional buds, and according to the treatment they receive. I advise your correspondent not to top his plants at all, but take out the flower buds as they form, and retain the three shoots as selected at the first break, and continue this system of treatment until the buds are "taken," which are to be retained for the production of the blooms. As to "lights" "red," or otherwise, they cannot be properly seen till turned on by the judges.—E. MOLYNEUX.]

### CRYSTAL PALACE SUMMER SHOW.

AN extensive, varied, and handsome Show was held in the Sydenham Palace on Friday and Saturday last, well maintaining the reputation of the establishment for meritorious displays. A different method of arranging the exhibits was adopted on this occasion, and proved advantageous in several ways. It has been usual before to have the greater portion of the plants together in the transept and one of the naves, but on Friday both naves and the transept were devoted to them, the result being that although the general effect was less imposing the interest was spread over a larger space, and the visitors were enabled to inspect the exhibits without being inconveniently crowded, as was often the case under the old system. There was, however, sufficient concentration of plants and classes in the transept to constitute an effective display alone, the groups of Calceolarias, Pelargoniums, and Roses being arranged on tables, and having a very bright appearance. Orchids were well represented; stove and greenhouse plants, Ferns, fine-foliage plants, and miscellaneous groups also contributed largely to the beauty of the Show. These were all arranged to the best advantage by Mr. W. G. Head, the Superintendent, and the sloping stages permitted the competitors to dispose their plants satisfactorily in banks; but it seemed somewhat too steep, and in a few cases a difficulty was experienced in placing the plants securely. This might be easily remedied by making the stages in short steps, and the plants could then be tilted at pleasure by means of wooden blocks. Stove and greenhouse plants were not quite so numerous as at summer shows usually, and in several instances the specimens were what are termed "one-sided," and though these were in healthy floriferous condition they did not look so well in small groups in the centre of the nave as they do in larger groups at places like the Regent's Park Botanic Gardens, where their defects are to a great extent concealed.

ORCHIDS.—Liberal provision was made for these plants, and the amateurs responded to the invitations freely. An open class was devoted to nine Orchids, Mr. A. G. Catt, gardener to W. Cobb, Esq., Silverdale Lodge, Sydenham, securing the premier award with specimens of medium size, but in excellent health and well flowered. Those shown were *Cattleya Mossiae*, C. Skinneri with ten racemes of bright flowers; *Laelia purpurata*, eight racemes; *Dendrobium thyrsiflorum*, with twelve long racemes; *Cypripedium Lawrencianum*, twenty flowers; *Odontoglossum citrosum*, five panicles; *Odontoglossum vexillarium*, very handsome, with twelve racemes of five and six highly coloured flowers each; *O. Alexandrae*, four racemes, a good variety, and *Dendrobium Bensoniae* flowering profusely. Mr. H. James, Castle Nursery, Lower Norwood, was second, showing several specimens similar to those he had at the Regent's Park Show two days before, the best being *Laelia purpurata*, eighteen flowers, a beautiful variety; *Dendrobium Jamesianum*, twenty-four large blooms; *Cattleya Mendeli*, twenty-two flowers; and *Vanda tricolor formosa*, five racemes. The third place was accorded to Mr. F. J. Hill, gardener to H. Little, Esq., The Barons, Twickenham, whose *Cattleya Skinneri*, *Aerides Fieldingi*, and *Lycaste Skinneri* were the most notable. A class for six exotic Orchids was also provided for amateurs, in which Mr. A. G. Catt was again the most successful competitor, but amongst the orchidist visitors there was some difference of opinion respecting the merits of the three collections entered. The first-prize plants comprised *Dendrobium thyrsiflorum*, two long racemes; *Laelia purpurata*, eight flowers; *Phalaenopsis grandiflora*, a handsome well grown plant with one raceme of flowers; *Cattleya Mendeli*, apparently a made-up plant, *Oncidium concolor*, and *Odontoglossum citrosum* being healthy samples. Mr. H. Luff, gardener to R. R. Hyatt, Esq., Hetherston, Leigham Court, Streatham, secured the second place with very neat and fresh specimens, not so large as the preceding but genuine plants; *Lycaste Skinneri* with twenty fine flowers, a very handsome plant, *Cypripedium villosum*, about thirty flowers; *Masdevallia Harryana*, sixteen flowers; *M. Lindenii*, forty flowers; *Phalaenopsis amabilis* and *Cattleya Mendeli*. These were the most meritorious of all in freshness. Mr. C. J. Salter, gardener to J. Southgate, Esq., Selborne, took the third prize with excellent plants of *Cypripedium Lawrencianum*, thirty-six flowers; *Dendrobium nobile*, *Masdevallia Veitchii majus*, a very fine variety, *Odontoglossum polyanthum*, *Odontoglossum vexillarium* with fourteen racemes, and *Dendrobium thyrsiflorum* with nine large racemes, but this plant rather damaged what was otherwise a good collection, as the foliage was somewhat discoloured. In the class for a group of not less than forty Orchids Mr. C. J. Salter was, however, victorious, gaining the principal prize with a choice and pretty collection of medium size but well grown plants, representing a large number of species and varieties. They were also very tastefully arranged with Palms and Ferns, forming a graceful combination of flowers and foliage. Some of the more notable plants were *Odontoglossum vexillarium*, *O. citrosum*, *O. Cervantesi*, *O. nebulosum*, *O. crispum*, *Dendrobium Devonianum*, *D. Falconeri*, and *Masdevallia ignea* and *Chimara*. Mr. James followed, his plants being rather larger with more *Cattleyas*, but there was not quite so much diversity in the group generally. Mr. Luff was third, *Odontoglossum vexillarium*, *Phalaenopsis Luddemania*, *Masdevallia Shuttlesworthii*, and *Dendrobium Falconeri* being well represented amongst many others. These exhibits together rendered the department for Orchids one of the chief features of the Show, and we do not remember seeing these plants so well represented at the Crystal Palace before.

STOVE AND GREENHOUSE PLANTS.—For single specimens Mr. C. J. Salter and Mr. E. Chadwick, gardener to A. M. Nelson, Esq., Hanger Hill House, were awarded equal second prizes for *Vanda suavis* and *Oncidium sphacelatum* respectively, the former a large plant with two racemes of flowers, and the other with six panicles. There were sufficient of these to add considerably both to the extent and beauty of the Show, although the competition was not quite so keen as at some previous shows. In the open class for nine specimens Mr. H. James was the most successful, having evenly trained examples of *Bougainvillea glabra*, globular and freely flowered; *Azalea Souvenir de Pays Bas*, freely flowered; *Erica Lindleyana*, 5 feet in diameter; *Aphelexis macrantha purpurea*, very bright; *Erica ventricosa coccinea*, *Anthurium Schertzerianum*, *Stephanotis floribunda*, *Erica Cavendishiana*, and *Darwinia Hookeri*. Mr. W. Chapman, gardener to J. Spode, Esq., Hawkesyard, Rugeley, was second with large, fresh, and healthy plants, but in several cases rather "one-sided," and not such even all-round specimens as might be desired for exhibition purposes, though useful for grouping in a house or elsewhere. Mr. Mould, Pewsey, took the third place for smaller plants, one of the best being *Boronia elatior*, capitally flowered. The best amateurs' six stove and greenhouse plants were from Mr. Chapman, and comprised *Tremandra ericifolia*, *Ixora coccinea*, *Hedera noliifera*, *Ixora Williamsi*, *Erica profusa*, and *Anthurium Schertzerianum*, all flowering freely. Mr. C. Rann, gardener to J. Warren, Esq., Handcross Park, Crawley, and Mr. J. Bolton, gardener to W. H. Spottiswoode, Esq., Combe Bank, Sevenoaks, followed in the order named, the former *Azalea Leopold I.*, *Erica depressa* and *Tetratheca ericifolia*, very fine, and the latter exhibiting *Clerodendron fallax* and *Statice profusa* in first-rate condition. Mr. H. James took the lead with a single specimen greenhouse plant, staging *Erica Cavendishiana*, 6 feet high, as much in diameter, very healthy, but not bearing a great number of flowers. Mr. S. Reece, gardener to R. Whyte, Esq., Pentland House, Old Road, Lee, was second with *Geuetyllis tulipifera*, 4 feet in diameter, globular in form, healthy, and well flowered. Mr. W. Chapman was third, showing *Aphelexis grandiflora*, 3 feet in diameter, and flowering most profusely. The best single specimen stove plant was *Ixora Diantha*, flowering freely; Mr. James was second with *Anthurium Schertzerianum*; and Mr. W. King, gardener to Philip Crawley, Esq., Waddon House, Croydon, was third with *Clerodendron Balfourianum*, of good size and in satisfactory condition.

The Azaleas from Mr. C. Turner, Slough, who was first in both classes for eighteen and nine plants. Most of the plants in the "eighteen" class were neat specimens, about 3 feet in diameter and most profusely flowered, the varieties bright and attractive. The most notable varieties were Mrs. Turner, soft pink and white; *Roi d'Hollande*, bright red, very effective; *Cordon Bleu*, warm purplish crimson; *Comte de Chambord*, blush and white, with a red blotch; *Madame Marie Lefebvre*, white, large, all these being single varieties, and *Duke of Edinburgh*, bright red, a double form of

great beauty. The larger specimens, which were 5 feet high, included Cheloni, Reine des Fleurs, Duc de Nassau, Stella, A. Borsig, Comtesse de Flandres, and Etendard de Flandres.

Roses, Calceolarias, and Pelargoniums, as already noted, formed imposing groups. The Roses from Messrs. Paul & Son, Cheshunt, Mr. C. Turner, and Mr. W. Rumsey were very handsome, and to these must be added the grand bank of plants, cut blooms, shown by Messrs. W. Paul and Son, Waltham Cross, but not in competition. The Calceolarias shown by Mr. J. James were dwarf handsome plants with large and brightly coloured flowers, Mr. C. J. Salter following with good plants bearing bright and diversely coloured flowers. Mr. C. Turner was the principal exhibitor of Pelargoniums; Mr. F. J. Hill and Mr. D. Phillips most of the other prizes in the open and amateurs' classes.

The leading exhibitor of fine-foliage plants and Ferns was Mr. C. Rann, who had some of the magnificent specimens that we have frequently had occasion to praise. His premier nine specimens included *Cycas revoluta*, *Croton interruptus*, *Dasyllirion acrotrichum*, *Anthurium crystallinum*, and *Bonapartea stricta*, which formed a grand bank in the transept near the large stage. Mr. J. N. Penfold and Mr. H. James followed with smaller examples. Mr. Rann's Ferns were also good plants. Crotons and Dracenas were numerous represented, but the former were somewhat deficient in colour. Mr. J. R. Bird and Mr. W. King won the chief prizes with vigorous plants. Mr. H. James had collections of *Sarracenia* and *Nepenthes*, for which first prizes were awarded. Messrs. Hooper & Co., Covent Garden, were awarded the premier prize for eighteen table plants, very neat examples of Palms, Dracenas, and other plants suitable for the purpose. Messrs. Laing & Co. were first with nine *Caladiums*, large well grown plants, such as are seldom seen at exhibitions.

Messrs. J. Laing & Co., Forest Hill, had a large and handsome group of miscellaneous plants, for which the first prize was awarded. It was one of the most tasteful and effective they have exhibited for some time, and excited the admiration of all visitors who saw it. A number of choice new Tuberous Begonias was included, together with many Orchids, Palms, Ferns, *Caladiums*, and innumerable other plants, amongst which were several novelties that were certificated. Messrs. Hooper & Co. were placed second with a group of *Petunias*, *Gloxinias*, *Azaleas*, and fine-foliage plants. For stands of flowers Mr. J. R. Chard, Clapham Common, was first in all classes with his usual tasteful arrangements. For collections of cut flowers Mr. A. Gibson, gardener to T. F. Burnaby Atkins, Esq., Halstead Place, Sevenoaks, and Mr. C. J. Salter were awarded the leading prizes, both showing well.

The miscellaneous non-competing exhibits comprised groups of Tree *Pæonies* from Messrs. J. Laing & Co., Roses from Messrs. W. Paul & Son and Mr. W. Rumsey, *Pelargoniums* from Mr. J. Wiggins, Crotons and *Mignonette* from J. A. Causton, Esq., West Dulwich; collections of Apples and hardy plants from Messrs. J. Cheal & Sons, Crawley, and floral designs from Mr. J. R. Chard and Mr. R. End. For all of the preceding extra prizes were awarded. Certificates were awarded for the following plants:—

*Pæonia Moutan odorata Marie* (J. Laing & Co.).—A large full-flowered variety of a delicate pale purple hue, and *lactea*, white, flower of great size and substance.

*Tuberous Begonia Marquis of Stafford* (J. Laing & Co.).—A handsome double, rich bright scarlet, the flower neatly formed.

*Tuberous Begonia Charming* (J. Laing & Co.).—Single, large beautifully formed rounded petals, white centre, with a deep rose margin.

*Caladium Comte de Germiny* (J. Laing & Co.).—A pretty variety with neat leaves, red with light spots, and *Raymond Lemonier*, red centre with pale yellow margin.

*Pelargonium Delight* (J. Wiggins).—A show decorative variety, white, with a crimson spot in each petal. Very attractive.

### MIGNONETTE IN POTS.

LARGE plants are not so commonly grown nowadays as was wont to be the case in years not so long past, for the simple and sufficient reason that small plants are much more useful. However, there are cases in which large plants are of greater service than small ones, and I am inclined to think that *Mignonette* for supplying flowers during early spring on till summer is one such case. This plant thrives on repression. Every flower spray removed is followed by three or more to take its place, so that literally the more flowers cut from a strong healthy plant of *Mignonette* the more flowers there are to cut.

A large plant well furnished with growth requires some time to lay a foundation to work on. Some growers allow a longer period than others, and I have no doubt that numbers will have not only sown the seed for next year's plants, but will have these plants in various stages of growth. For my part I own to a repugnance to nursing hardy flowers under glass at an early stage of their existence, though there are of course instances in which it is necessary; but for one case in which a necessity can be admitted there are numbers in which no such necessity exists, and I have to submit that the case of raising *Mignonette* in early spring belongs to the latter category. Seeds sown in May germinate strongly, and, other things being equal, plants from such seed will ultimately overtake those from seed sown earlier and grown on under glass for a time.

The cultural details of *Mignonette*-growing is simple enough, and it will not be necessary to enlarge on them at any length. The seeds are sown in thumb-pots, three seeds in each, the plants from which are reduced to one. The compost used for the seedling pots is one of equal parts loam, Mushroom bed refuse, and sand. The pots are shaded from sun until the seedlings are up, and even afterwards until the plants have been shifted, the one thing which is to be most guarded against in the case of this flower being dryness of root, and in the case of very small pots it is safer to err by keeping the sun off them altogether than to risk any likelihood of the young plants being subjected to a drying. Very good plants can be formed and flowered in 10-inch pots, and the summer treatment of the plants consists in shifting on into large pots

until the above size is reached, and in pinching out any flowers which may appear. The shifts may be from the seed pots in those 4 inches across, next into those of 7 inches diameter, and then into the largest pot. In shifting none of the drainage should be removed from the ball, as so many roots cling thereto as to cause its removal and act prejudicially on the health of the plant. The material we use for potting is composed of three parts loam to one of rough Mushroom bed refuse. A layer of the latter is also placed over the drainage, and in potting the soil is kept rather loose than firm. Occasional surface dressing of a good artificial manure is of much benefit throughout the summer months, the only time when they must be left off being during the time subsequent to repotting, when fresh roots have not had time to push into the fresh soil. During the winter months when growth is merely kept going very little manure must be employed, but immediately the days begin to lengthen the plants may be hastened into bloom, and manure every ten days will then be of very great advantage.

There are various methods of training, but I do not think any is better than the bush form. Plants trained in this way can be cut on occasion very hard indeed without damaging their appearance to any great extent, and it has the further advantage that once the foundation of the bush has been formed the after training does not call for so much attention as some other methods. I may refer to one little habit of this plant, which in the hands of the less experienced causes a good deal of annoyance throughout the summer months, and that is the difficulty of keeping the plants from going altogether to flower. It is a continual pinching of flower tips all along, and after the portion covered with flower has been removed very little fresh growth extension is left behind. The only escape out of this difficulty is to keep up a vigorous root-action, such as under ordinary care would be secured by carrying out the details noted above, when there will be less tendency to flower displayed by the growths, and strong healthy shoots with ample foliage will follow. As to the best variety to grow, my experience would point to selecting a good type plant, and saving seed therefrom. At present I am saving seed from a market-grown plant, the stock in the hands of market florists being very good.

It is possible to secure a grand supply of flowers by sowing seeds in a heated low frame about the new year. A very rich bed of soil is made up, the seed sown thinly. The plants, which appear about the middle of January, can be pushed on at a moderate rate, and by the latter part of March begin to furnish a supply of flowers which never fails so long as they are removed as they become ready, and occasional dressings of manure given, nitrate of soda causing a very luxuriant growth.—B.

### ALPINE AURICULAS.

It is not my intention to speak of the florists' varieties of Alpine Auriculas, as I am not sure they would succeed under the treatment I am about to recommend; at any rate they are generally speaking much more carefully treated, but many people cannot find the time and convenience which the florist requires, and yet they might have a display of flowers which would compare very favourably with the others if not minutely inspected.

I was forcibly reminded a few days since when looking round Burghley Gardens, how easy it is to get a good display of these Auriculas if they are only planted in a favourable position; two rows of them on a north border were worth seeing, and yet they have received no special attention. If memory serves me rightly the seed was sown in 1880; the seedlings were planted when large enough in their present position, which is a north border shaded from sun by trees; soil a rich deep sandy loam, and beyond keeping them clear of weeds and rubbish they have received no attention since that time. They are now huge plants carrying fine trusses of flowers, and almost everyone would be glad to have a similar display of flowers so varied in colour and sweet-scented. The seed is best sown as soon as ripe in a pan, and placed under a handglass where the sun never shines, or, failing such a position, in the coolest place obtainable. Shade them and keep the soil well watered until the seedlings are up, when they should have as much light as possible without bright sunshine, and a little air. As soon as they are half an inch high they should be pricked out into other pans, and are best if kept in a cold pit through the first winter in order to be safe from slugs, otherwise they are quite hardy and may be pricked out in a cool shady position if slugs can be guarded against.

A few of the plants will flower the first spring, but the majority will require another season's growth. They should be planted in their permanent quarters when about twelve months old, and afterwards, if kept clear of weeds, will take care of themselves for several years. Those at Burghley were certainly the finest I have ever seen. It is not in everyone's power to find them a position where the sun never shines upon them, but much may be done by shading them when in flower if they are in a warm position, and watering and mulching in summer. Several years since I saw some very good plants grown in that way in a dry and warm position. They like a deep rich soil, and will repay for any extra attention.—W. H. DIVERS, *Ketton Hall*.

### DENDROBIUM FIMBRIATUM OCULATUM (PAXTONI.)

ONE of the most handsome of the racemose *Dendrobiums* is *D. fimbriatum oculatum*, or *D. Paxtoni* as it is very generally called in gardens, and with good treatment it develops into a particularly fine specimen, the long pendulous racemes drooping gracefully round the plant. The colour of the flowers is a rich golden orange with a crimson maroon blotch, the

racemes being somewhat lax and the flowers distantly placed upon them compared with such well-known *Dendrobiums* as *densiflorum* and *thyrsoflorum*. There has been some confusion respecting the so-called *D. Paxtoni*, a name which has been applied to two distinct plants, and is now not accepted for either. *D. Paxtoni*, as described and figured in "Lindley's Botanical Register," t., 1299, is really *D. chrysanthum*, and is easily recognised by the flowers being borne two or three together instead of in racemes as in the *D. Paxtoni* of gardens. The latter is figured in "Paxton's Magazine of Botany," vol. 6, t. 169, under that name, and in Paxton's "Flower Garden," vol. 3, t. 84, under its true name

whole collection is in most satisfactory condition. All the *Dendrobiums* are placed in the warmest house when making their growths, and are freely supplied with water at the roots. When at rest they are kept cool and quite dry, and it does not matter if they shrivel a little at that time. As soon as the flower spikes begin to push out from the pseudo-bulbs water is again applied freely. It may be added that the *Dendrobium* specially referred to is growing in a pot 8 inches in diameter, and very rarely is so fine a plant seen in a pot that size—the best proof that the culture is exactly what the plant requires.

There are several other fine specimens in the Great Gearies collection,

Fig. 76.—*DENDROBIUM FIMBRIATUM OCULATUM*.

*D. fimbriatum oculatum*. The former of these two is said to have been found by Mr. Gibson, "growing on trees at Pondooah at the base of the Khoseea Hills." It was introduced to the Chatsworth collection in 1837, and flowered in June, 1838.

The illustration (fig. 76) was prepared from a drawing of a very handsome specimen grown by Mr. J. Douglas, gardener to F. Whitbourn, Esq., Great Gearies, Ilford, which is one of the finest we have seen for some time. The plant in question had forty-nine racemes of flowers expanded at the time the drawing was taken, and its beauty can be readily imagined. Mr. Douglas knows full well how to grow Orchids, and the

which we may have occasion to refer to, for some have already made a mark at the leading exhibitions.

#### ROYAL HORTICULTURAL SOCIETY.

MAY 25TH.

THE first of the series of Shows announced for the present season by the above Society was held on Tuesday last in the conservatory, South Kensington. Roses were capitally represented together with Orchids, Azaleas, and Pelargoniums. The collections of hardy flowers also furnished substantial and handsome groups, to which much space was devoted. Stages in the centre of the conservatory extending the whole length were occupied with the principal competing exhibits, the hardy flowers, Cucumbers, Melons, and

Australian Apples being arranged on the side tables. Amongst the hardy flowers the Tree Pæonies were the leading attraction, Mr. Ware having a large collection of varieties of many bright and delicate shades of colour.

**ROSES.**—Substantial prizes of £8, £5, and £3 were offered in the class for twelve Roses, not less than ten varieties, in pots not exceeding 9 inches in diameter. Messrs. Paul & Son, Cheshunt, were awarded the first prize with dwarf compact plants of medium size, about 3 feet in diameter and flowering freely. The chief varieties were White Baroness, Edouard Morren, Madame Lacharme, Merveille de Lyon, Etoile de Lyon, and Lord Frederick Cavendish, very bright and fresh. The second prize was awarded to Mr. C. Turner, Slough, for slightly smaller plants but very healthy; Camille Bernardin, Beauty of Waltham, Innocente Pirola, and Comtesse de Serenye were especially notable. Mr. William Rumsey, Waltham Cross, was third with still smaller plants.

**ORCHIDS.**—Two classes were devoted to Orchids, both for nine distinct plants from amateurs and nurserymen respectively, the prizes being the same in each case—namely, £5, £3, and £2. In the amateurs' class, Mr. Hill, gardener to H. Little, Esq., The Barons, Twickenham, was first, showing Cattleya Skinneri, with twenty flowers, Dendrobium thyrsiflorum, with two dozen racemes; Dendrobium densiflorum, five racemes; D. Dalhousianum, seven racemes; Aerides Fieldingi, Cattleya Mendeli, Lælia purpurata, and Cattleya Mossiae varieties. Mr. A. Luff, gardener to R. R. Hyatt, Esq., Hetherst, Leigham Court Road, Streatham, was second with similar plants to those he showed at the Crystal Palace. In the nurserymen's class, Mr. H. James, Lower Norwood, was the only exhibitor, taking the first prize. His Cypripedium Lawreucianum with thirteen flowers, Cattleya Mendeli with over twenty, and Dendrobium Jamesianum were the best plants.

**AZALEAS.**—This is just the best time for Azaleas, and though the number of exhibitors is not very great, a few contributions add wonderfully to the brightness of a show. The classes provided were for twelve Azaleas not less than ten varieties, and for six Azaleas from amateurs, the pots in both classes not to exceed 9 inches in diameter, but the amateurs were unrepresented, Mr. C. Turner gaining the premier prize for twelve Azaleas with his dwarf, globular, fresh, handsome plants of the most effective varieties. Roi d'Hollande, Cordon Bleu, Mrs. Turner, Bernhard Andreas alba, Mdlle. Marie Lefebvre, and grandis were the most effective.

**PELARGONIUMS.**—Mr. C. Turner was the premier exhibitor in the class for eighteen Pelargoniums of any variety in 8-inch pots. Many of the plants were over 4 feet in diameter and grandly flowered. The best varieties were Kingston Beauty, Emperor of Russia, Prince Leopold, Rosetta, Mous. Desmoulins, Duchess of Bedford, Madame Thibaut, Rosy Morn, Comtesse de Choiseul, Gold Mine, and Maid of Honour. Mr. H. Little was placed second with much smaller plants, but well grown and flowering profusely, especially the free Duchess of Edinburgh and Duchess of Bedford; other good varieties were Pink Perfection, G. Sheppard, Mauve Queen, E. J. Perkins, and Lady Isabel.

**CARNATIONS AND CALCEOLARIAS.**—Only one collection of Carnations was staged, Mr. C. Turner securing the first prize with strong plants, including a large number of seedlings. The bright yellow Pride of Penshurst and the rich scarlet Rufus were also handsome. The only collection was from Mr. A. Luff, who was awarded the second prize, the plants of medium size, but bearing good flowers of varied colours.

**MISCELLANEOUS.**—The Roses from Messrs. W. Paul & Son, Waltham Cross, formed an important exhibit. A dozen boxes of fresh and beautiful cut blooms were staged, and a large bank of plants similar to those which were so much admired at the previous meeting (silver Banksian medal). A large group of Roses in pots was also contributed by Messrs. Paul and Son, Cheshunt, and comprised good specimens of Centifolia rosea, John Stuart Mill, La France, and Comtesse de Serenye, with many other smaller plants (silver Banksian medal). Messrs. H. Lane & Son, Berkhamsted, showed groups of Azaleas and Rhododendrons of many varieties and profusely flowered (silver Banksian medal).

Mr. T. S. Ware, Tottenham, had an extremely effective and handsome group of choice hardy flowers, including an extensive collection of Tree Pæonies in many varieties, with Lilies, Tulips, the pretty white Ranunculus acrifolius fl. pl., Gentians, Phloxes, Dodecatheons, Trollius, the beautiful Polemonium Richardsoni, and many other choice plants (silver gilt medal). Messrs. Barr & Son had an extensive group of hardy flowers, Irises, Scilla nutans in variety, Pæonies, and Narcissi being largely shown (silver Banksian medal).

Mr. Cummins, gardener to A. H. Smee, Esq., The Grange, Wallington, was awarded a bronze Banksian medal for a group of Cattleyas, representing a number of varieties of C. Mossiae, some fine forms of Odontoglossum Alexandræ, Masdevallia Shuttleworthii freely flowered, a good variety of Masdevallia amabilis, and several other choice plants. Mr. J. James, Farnham Royal, exhibited a group of dwarf handsome Calceolarias of his superb strain (bronze Banksian medal). Mr. W. Rumsey, Waltham Cross, was awarded a bronze Banksian medal for eight boxes of cut Roses, representing many varieties. A bronze Banksian medal was also awarded to Messrs. Green & Nephew, 107, Queen Victoria Street, for their elegant flower glasses and vases.

**SPECIAL PRIZES.**—Messrs. Sutton & Son, Reading, offered three prizes for the best brace of either Purley Park Hero or Improved Telegraph Cucumbers, which were won by Mr. T. Lockie, gardener to the Hon. G. O. Fitzgerald, Oakley Court, Windsor; Mr. W. Robins, gardener to E. D. Lee, Esq., Hartwell House, Aylesbury; and Mr. J. Neighbour, Bickley Park Gardens, the six competitors showing fruits of nearly equal merit. They also offered the same number of prizes for the best brace of Melons, either Imperial Green Flesh, Scarlet Invincible, or Hero of Lockinge, each entry to consist of one variety. First Mr. Lockie with Hero of Lockinge, of medium size and well netted; second Mr. H. W. Ward, gardener to the Earl of Radnor, Longford Castle, Salisbury; and third Mr. G. Malcolm, Willington Hall, Tarporley, Cheshire, with the same variety. There were four competitors.

Messrs. James Carter & Co., High Holborn, contributed three prizes, "open to noblemen's and gentlemen's gardeners and amateurs only," for the best brace of Carter's Model Cucumber. The prizes were won by Mr. T. Lockie, gardener to the Hon. G. O. Fitzgerald, Oakley Court, Windsor; Mr. C. J. Waite, gardener to Col. the Hon. W. P. Talbot, Glenhurst, Esher;

and Mr. J. Neighbour, Bickley Park Gardens, Kent. There were seven competitors, all showing good even samples.

**FRUIT COMMITTEE.**—Present—T. Francis Rivers, Esq., in the chair, and Messrs. John E. Lane, Harry J. Veitch, G. T. Miles, W. Denning, T. J. Saltmarsh, John Woodbridge, William Warren, John Burnett, T. B. Haywood, Philip Crowley, Harrison Weir, R. D. Blackmore, G. Bunyard, Arthur W. Sutton.

The principal exhibits before this Committee were the Apples and Pears from Australia, which are mentioned in another column. The South Australian Commissioners showed some Oraanges and some large handsome solid Pears, which were highly commended, the weight of three fruits being respectively 2 lbs. 12 ozs., 2 lbs. 14 ozs., and 2 lbs. 15½ ozs. each. Mr. J. F. Pascoe, South Australia, showed Apples Dumelow's Seedling and Garibaldi, a vote of thanks being accorded for the latter. Mr. R. Davenport, South Australia, exhibited excellent specimens of Apples Stone's Pippin, Pomeroy, French Crab, and Pear Napoleon, with a dish of Medlars, the Apples being highly commended, and a vote of thanks accorded for them. Mr. S. A. Bucholz, New South Wales, sent bunches of Grapes Black Prince and Black Sherry, of good size and in excellent condition; also three varieties of Apples, which were highly commended. The Committee also expressed their opinion that the Grapes named were excellent in quality and condition, particularly the so-called Black Sherry, respecting which they desired further information as to its origin. Messrs. Eyles, Bros., New South Wales, contributed twelve varieties of Apples that were highly commended, especially Nonpareil and Reinette de Canada. The Committee recommended that a Knightian medal be placed at the disposal of Sir Alexander Stuart for the above and other collections.

The other exhibits were not numerous, but Mr. C. Herrin, Chalfont Park Gardens, Gerrard's Cross, was awarded a cultural commendation for a collection of handsome Citrons, the fruits 5 and 6 inches in diameter. Mr. T. Lockie showed fruits of a seedling Melon from a cross between Hero of Lockinge and Sutton's Invincible, which was passed. Mr. W. Chettleburgh, Worstead House Gardens, Norwich, showed solid examples of Carter's Golden Tripoli Onions. Messrs. J. Veitch & Sons, Chelsea, had fruits of Bismarck and Sandringham Apples to show how well they keep, and W. W. F. Huncie Dick, Esq., Thames Ditton House, Thames Ditton (gardener, Mr. W. Palmer) had two braces of Melons, High Cross Hybrid and Scarlet Premier, apparently good fruits, but it was stipulated that they should not be cut.

**FLORAL COMMITTEE.**—Present, James O'Brien, Esq., in the chair, and Messrs. Shirley Hibberd, Richard Dean, George Paul, J. Dominy, H. M. Pollett, H. F. Lendy, Jas. Douglas, E. Hill, H. Bennett, W. Bealhy, W. Wilks, Amos Perry, H. Ballantine, James Hudson, James Walker, H. Herbst, H. Cannell, W. B. Kellock, William Holmes, H. Turner, and Thos. Baines. Mr. C. Turner, Slough, had a collection of new and choice Pelargoniums, show varieties, the most attractive being Margaret, crimson, white lower petals; The Czar, scarlet and maroon; Magnate, deep maroon and pink, with a white centre; Mandarin, brilliant scarlet; and Outlaw, rosy salmon and maroon. Mr. Wiggins showed a group of Pelargoniums, similar to those he had at the Crystal Palace. Messrs. Hayes, Edmonton, exhibited some new show decorative Pelargoniums; Princess Maude pink and white, and Albert Victor rosy pink edged with white, were the two principal varieties. Mr. B. S. Williams, Upper Holloway, exhibited a group of new plants, several of which were certificated; others not so honoured were Oncidium tetracopis with very long paucules and brownish flowers, the petals yellow, spotted brown, something like O. macranthum in habit. Lælia Russelliana, with white sepals and petals, and a pale purple lip, and L. purpurata Regina with a deep crimson purple lip, and pale purple sepals and petals, were the most notable. Major Lendy, Sunbury (gardener, Mr. West) was awarded a cultural commendation for Saccolabium curvifolium with sixteen spikes of orange red flowers, and a number of spikes of Lælia purpurata, Mr. A. Luff had a curious variety of Cattleya Mossiae named marmorata, spotted and streaked with crimson and white. A vote of thanks was accorded to Messrs. Laing and Co., Forest Hill, for Dendrobium Devonianum with two long growths crowded with flowers. H. Little, Esq., showed a plant of Cattleya Trianae Littleana with white flowers, the lip golden yellow in the throat. Also a pretty variety of Cattleya Mendeli named Masterpiece, the flowers large, nearly white, with a blotch of crimson on the lip. Messrs. Hooper and Co., Covent Garden, showed a good double pink Petunia named Empress, very free and bright. Messrs. J. Carter & Co., High Holborn, had a group of plants of their Queen's Prize Mimulus, the flowers of considerable size and richly coloured, crimson, rich scarlet, orange and yellow spotted. Messrs. E. H. Krelage & Son, Haarlem, were awarded a vote of thanks for a collection of cut flowers of Tulips varied in colour and markings.

#### CERTIFICATED PLANTS.

*Cattleya Mendeli Duke of Marlborough* (F. Sander & Co.).—A magnificent variety with large flowers, the petals about 3 inches broad faintly tinted with purple, the lip over 2½ inches across, gold veined in the throat, the apical half intensely rich crimson, running round the margin and undulated at the tip.

*Odontoglossum vexillarium Sunrise* (H. M. Pollett, Esq.).—A pretty variety, the flowers flushed with crimson, and the sepals and petals tipped with white.

*Houlletia odoratissima antioquiensis* (B. S. Williams).—A curious Orchid, with a scape of five flowers, the sepals and petals reddish brown, the lip white, contracted in the middle with two curved brown horns at the base.

*Amaryllis Her Majesty* (B. S. Williams).—A remarkable variety of the A. reticulata type, the flowers of good shape, and deep crimson right up to the centre.

*Gloxinia Miss Cannell* (H. Cannell & Sons).—An erect-flowered variety, with large blooms, white, with a ring of bright purple at the top of the tube.

*Pelargonium purpurea* (C. Turner).—A free and handsome variety of Mr. Foster's raising. The flowers large, deep crimson, white centre, and the lower petals bright pink.

*Pæonia Moutan Madame Laffay* (T. S. Ware).—An immense flower, 9 inches across, a grand variety, the colour a soft rosy crimson.

*Lithospermum graminifolium* (T. S. Ware).—A species with linear leaves, 2 inches long, and small heads of bright blue tubular flowers.

## SCIENTIFIC COMMITTEE.

Sir J. D. Hooker in the chair.

*Rhododendrons*.—Hon. and Rev. F. Boscawen exhibited five branches of *R. arboreum* "improved," being a hybrid between *R. arboreum* and *R. atro-sanguineum*. The trunk stands well above the foliage, and is more continuously flowering than *R. arboreum*. The tree is now 15 feet high.

*Malformed Parsnip*.—Mr. Smith exhibited a specimen which had grown through the neck of a medicine bottle; the result was a quaint hourglass-like form.

*Crybe rosea*.—Mr. O'Brien suggested that the Orchid so named and exhibited at the last meeting was probably an *Ambuletia*. He also exhibited for Dr. Duke, of The Glen, Lewisham, a fine plant of *Catasetum atratum*.

*Liparis Loiseilii*.—Mr. Ridley exhibited plants of this Orchid; the pot in which the rhizomes had been was allowed to become perfectly dried; but in breaking up the earth and watering this spring they have recovered and are flourishing vigorously. Colonel Clarke remarked on the tenacity of life of Orchid bulbs (*e. g.*, *O. Morio*) under great drought.

*Ophrys Bertolonii*.—Mr. Brockbank exhibited a specimen of this *Ophrys* received from Nice.

Fig. 77.

*Tobacco cultivated in Great Britain*.—Colonel Clarke exhibited dried leaves of various kinds—1, Plants sown early and gathered early of yellowish brown colour (1884); this was the best quality. 2, Plants left too long in the ground, the leaves being much longer and greener. 3, *Nicotiana rustica*, a very coarse form. 4, Hybrid between *N. rustica* and the Havana Tobacco. It bore the form, habit, and colour of the latter.

*Elms*.—Prof. Boulger showed a fruiting branch of a tree from Barham Court Park (R. Lee, Esq.), supposed to be a "Wych" Elm; but Mr. Boulger observed it has many suckers, is very smooth, with the seed vessel above

Fig. 78.

Fig. 79.

the middle of the samara, and therefore it belonged more nearly to *Ulmus campestris*. He believed it to be *U. laevis*.

*Gall on Violet*.—He also showed a specimen of gall of *Cecidomyia violae*, from Kent, which in 1884 was found in Essex, and believed to be new to Britain. It occurred on *V. sylvatica*.

*Ecidium on Chives*.—The following communication was received from Mr. Plowright:—Mr. Phillips two years ago drew attention to a *Puccinia* accompanied by uredospores upon Chives, which he found near Shrewsbury. This was called *Puccinia mixta*, *Fckl.* Dr. George Winter, however, classes it with other *Medines* upon various allied species of host plant under the name *Puccinia poeri* (Sow). Later in the same year I found specimens of this *Puccinia* upon Chives at Downham. During the present month (May) on visiting the Downham habitat I was fortunate in finding upon plants which bore the *Puccinia* the *ecidiospores* which answer Dr. Winter's description. The *Ecidium* is distinct from the *Ecidium* on *Allium ursinum*, which has an heteroecismal origin.

*Red-spotted Potatoes*.—Mr. Plowright also sent the following remarks on this subject:—In 1884 it will be in the memory of the Committee that a number of tubers grown at Chiswick in connection with the Jensenian experiments, which were found upon section to be spotted inside, as if from the effects of the *Phytophthora*; so much, indeed, did they resemble truly diseased tubers, that some members of the Committee regarded them as such. Specimens were, however, sent to the three gentlemen in Europe to

whom we owe the most of our knowledge of the Potato disease—namely, to Professor De Bary of Strassburg, Dr. J. Kubn of Halle, and Mr. Jensen of Copenhagen. Without throwing any light upon the true nature of these spots, all three of these gentlemen were unanimous in their opinion that the spotting was entirely unconnected with the *Phytophthora*. An instance of this spotting disease came under my notice the same year near King's Lynn, and I took the opportunity of making a few observations upon the affection. First and foremost, although resembling the *Phytophthora* spots in colour, there is this great difference. The *Phytophthora* spots always originate upon the surface of the tuber and pass inwards, this being, as De Bary has long ago shown, the essential nature of the disease. Secondly *Phytophthora* spots are soon followed by decay (wet rot), the spotted tubers under discussion do not tend to decay at all. I had under observation about half a bushel of suspected tubers, for the tubers show no indication of the spotting until they are cut open, from October till May, but none of them showed any signs of decay. I obtained these tubers from the grower who resided near King's Lynn, and who suffered considerable loss from the affection, because it was impossible to tell how many were spotted until they were cut open; the consequence was that the crop was unsaleable, and, as a matter of fact was used for feeding pigs.

In the following spring (1885) my tuber began to sprout just as healthy tubers would.

On the 24th May (1885) five tubers were selected, which on section showed the internal spotting in a very marked degree; they were planted in my garden and carefully watched. In due course they threw up healthy shoots, which bore healthy leaves and grew in all respects as healthy Potatoes ordinarily grow. On the 16th October they were dug up and examined. They had produced forty-eight tubers, each of which was cut up into slices and closely examined for the internal spots, but not a trace of the disease could be detected.

Hence it would appear that, whatever may be the nature of the affection which gives rise to this internal spotting, it cannot be very readily trans-

Fig. 80.

mitted to the young tubers by using diseased sets, and although this negative result is all that I was able to arrive at, yet it seemed to me of sufficient interest to lay before the Scientific Committee.

*Deutzia scabra, Blind Flowers of*.—Mr. Henslow reported on his examination of these flowers, brought to the last meeting by Dr. Lowe, and found that they differed from the normal flowers in the following particulars. The sepals were much smaller, as also were the petals. The stamens had short filaments entirely devoid of the wing-like appendages in the usual flowers; the anthers were shrunken and devoid of pollen. The ovary was much smaller, with the placentas incoherent in the axis, and with rudimentary ovules; the style much shorter; and lastly, the stigmas smooth and not papillose. One or two normal flowers were occasionally present on the same raceme as the abnormal. The conclusion drawn from the above appearances was that from some unknown cause the flower buds had been insufficiently supplied with nutriment, causing arrest of structure in every part of the flower. Col. Clarke observed that he had frequently noticed that the earlier flowers were reduced in size, but as the season advanced the normal flowers followed, so that those sent by Dr. Lowe represented a still further reduced condition—no doubt caused by atrophy.

## HEATING SMALL GREENHOUSES AND FRAMES.

WE have received a circular from Mr. Toope of Stepney, in which we find representations of heating small amateurs' greenhouses, and also ordinary garden frames, with a request that if we see anything novel or good in them to bring them to the notice of our readers. The frame heater, fancifully called the "Little Vixen," is, so far as we know, quite new. It is a small gas or oil-heated boiler placed outside, with pipes conducted through or round the frame for heating it, as shown in fig. 77. The plan and section (fig. 78) show the boiler, which, including the lamp, is only 1 foot high and 7 inches in diameter, this size having been heating a frame satisfactorily for some months, the roughest winds not blowing out the light. We think this appliance should be exhibited at horticultural shows and meetings, as a safe, certain, and inexpensive frame heater could scarcely fail to meet with acceptance by gardeners and amateurs, as enabling them to turn their garden frames to useful account in winter as well as summer.

The "Champion Heater" for small greenhouses appears to differ from others we have seen in the method of heating the water. The flame (from gas or oil) strikes directly on the water at the top of the

boiler, the heated water expanding and passing at once through the flow pipe into the house. The heat is then forced downwards into the soot box, rising upwards again through the water, the fumes of combustion passing to the open air through a pipe at the top. By this arrangement it is claimed that the greatest possible amount of heat is absorbed by the water, the proof being that the "outlet pipe for the fumes being cooler than the hot-water pipes" in the house. The plan and section fig. 79 show the principle of the boiler, the arrows indicating the vertical transit of the heat. Fig. 80 shows the apparatus with pipes attached from both sides, but, as the circular indicates, they can be led from either side according to the arrangement of the structure to be heated. The necessities of an amateur led to its production, who desired to heat his greenhouse inexpensively with a minimum of trouble to himself, while producing a sweet atmosphere for his plants. A hot-water heated propagator is also illustrated in the circular in question, and is well adapted for raising plants from seed or cuttings at any season of the year.

#### KITCHEN GARDEN.

**OLD TOMATO PLANTS.**—Where plants have been growing and fruiting for some time in 8½ or 10-inch pots or boxes, they may now be showing signs of having done all they can in their confined rooting space, as well as having filled all the room available for the top growths; but we should not advise such plants to be thrown away as being of no further use, because if they are planted against a wall in the open air they will soon recommence growing and fruiting, and they will mature quantities of fruits long before any can be gathered from young plants in the open. The old plants will not look so well as the young ones, but early fruit, and plenty of it, is the object to aim at, and the old plants are the best for this. They should have rich soil, and the shoots must be tied up carefully. Under glass the shoots of these may have been constantly restricted, but they must be allowed to make fresh growth in the open, and as soon as a quantity of fruit has been formed, crowding of the wood must again be avoided.

**THINNING YOUNG VEGETABLES.**—The recent excellent rains have caused young vegetables to grow very rapidly, and we must again call attention to timely thinning. Just now is a busy time in all departments, and some may be inclined to think that so long as the seed is sown and the plants growing, progress is being made, but if the plants are allowed to be crowded in the beds or rows they will receive a check from which they will not readily recover, and it may end in inferior produce being grown where only good first-class crops ought to have been found.

**ONIONS.**—We never remember so few of the autumn-sown Onions throwing up flower stems as this spring. Out of some thousands growing rapidly at the present time there are not a dozen showing flower. This satisfactory state of matters is, we hear, very general, and the autumn-sown Onion crop will be a very remunerative one this spring and summer. Some of the White Elephant type, which are very early, are now ready for use, as they have formed bulbs several inches in circumference. We have this week finished our summer crop of last year. James' Keeping remained longest in sound condition, but like some others, they at last began growing, and had to be thrown away. Spring-sown Onions are late, but the seed has germinated freely and the plants are healthy. It is now the maggot is apt to appear, and every effort should be made to suppress it. It is a bad plan to allow it to destroy some of the plants and then try to check or exterminate it. Prevention is much better than cure in this case, and whether its presence is suspected or not, the plants should be dusted freely with soot once a week until the bulbs are well advanced in growth. If this can be done during rain so much the better. A little salt or guano may be mixed with the soot with advantage. Some growers thin their Onions; others do not. When we desire to have large bulbs for show or any special purpose, we thin them to 6 inches or so apart, but the general crop for kitchen use is seldom thinned, and although the bulbs may develope until they are almost growing on the top of each other, they still become of a very useful size, and for a heavy crop there is no better way of growing them than this.

**ENDIVE.**—While Lettuces are in demand for as long a season as possible Endive is not so much valued at all times, and a supply of it from August to September until the new year, or thereabouts, is generally as much as anyone desires. It is a very acceptable addition to salads. The Green Curled variety, or forms of this, are most ornamental, but the Broad-leaved Batavian is the hardiest, and should be grown late. A small patch of seed will produce a great many plants, and if sown at once the plants will be ready for transplanting by the end of June, and will become useful in August. At that time, however, it is not long in running to seed, and only small batches should be sown or grown at a

time. If a little seed is sown at intervals of a fortnight or three weeks a constant succession will be easily kept up.

**PEAS.**—American Wonder in the open is now in pod, and although there is none of the gather-and-come-again character about it, it will soon furnish a good dish. Where taller varieties are in bloom, and it is desired to have them in as soon as possible, take the points out of each of the main growths. This will cause the pods to fill rapidly. Earth up and stake all advancing crops, water freely in dry weather. Late varieties should now be sown in quantity. Give them a deep rich soil and sunny position. Some approve of sowing early varieties for late use; we do not, and adhere to such good sorts as Laxton's Omega, Sutton's Latest of All, and Ne Plus Ultra. Peas generally promise to be good.

**CHICORY.**—This is no use in summer, but when large roots are produced before autumn, and these are lifted and forced in a dark place, a most delicious salad matter is readily produced in quantity. To have it in good condition the seed should be sown now. We always sow a few rows in any odd corner of the garden where the soil is deep and rich, and it never fails. The seed should be sown in rows 15 inches apart, and 2 inches below the surface. When the young plants come up they should be thinned to 6 inches apart, and summer culture consists in keeping weeds down by the use of the Dutch hoe.

**PARSLEY.**—There is no more important crop in the kitchen garden than this. Its absence creates inconvenience everywhere. A supply must be forthcoming. Old roots have been throwing up plenty of leaves lately, but the flower stems are also appearing, and as these roots must keep the cook going until the spring-sown plants are ready, the flower stems should be cut down as fast as they appear. Seedlings are now about 2 inches high, and this is an excellent time to transplant quantities of them. Patches should be planted all over the garden, as if one lot fails another may succeed, and if a row is put in along the edge of a walk, or the bottom of a wall, or at the end of any crop where there is not sufficient space to plant anything bulky, it is surprising the excellent quantities of Parsley that will be produced. This crop will bear and be benefited by the same treatment as the Onions in dusting soot and other fertilisers over the plants in damp weather.

**RIDGE CUCUMBERS AND VEGETABLE MARROWS.**—These are now beginning to grow freely in the open. Do not protect them any longer than is necessary, and begin training the shoots out from the first. Crowding must be avoided, and pegging down or tying must be practised early. Where the growths are running down the sides of mounds, a few branches should be put round the bottom of the heap, when the growths will scramble over them, and the fruit will form freely and remain clean amongst the branches.

**PLANTING OUT CAULIFLOWERS.**—Brussels Sprouts, Cabbage, and all plants of this class should be inserted as the plants become ready and the ground vacant. Those transplanted during wet weather never fail to do well.

#### FRUIT FORCING.

**PEACHES AND NECTARINES.**—*Early House.*—Trees of the very early varieties, such as Alexander, Waterloo, and Early Beatrice, will now or soon be cleared of the fruit. The shoots on which the fruit has been borne, and not being required for the extension of the trees, should be cut away to admit of the full exposure of the foliage to light and air. Syringe forcibly to cleanse the foliage of red spider, and if this and scale continue troublesome the prompt application of an insecticide will be necessary to eradicate those pests. It is highly important that the foliage be kept healthy, and to prevent over-maturity or premature ripening of the wood it is necessary to keep the house as cool as possible by ventilating to the fullest extent after the fruit is gathered. The borders, floors, &c., should be kept moist, and in showery weather remove the roof lights. Keep gross laterals stopped, but avoid giving a check by a great reduction of foliage at one time, as this has a tendency to hasten the ripening of the growth, and when this is the case the trees will be swelling the buds through over-development when they should be going to rest. Trees of Hale's Early, A Bec, Early York, and Early Grosse Mignonne, with Royal George in the same house or in a house to themselves, which is much the best, will be ripening their fruit, and must not be syringed, though if the trees become infested with red spider a thorough syringing may be given when there is a prospect of a fine day, as with the water hanging any length of time the skin is liable to crack in fruits that are partly ripe, whilst those that are nearly ripe will be much deteriorated in quality. The trees must not be allowed to suffer by want of water at the roots, but any excess of moisture at this stage has a tendency to cause splitting at the stone.

*Houses Started Early in January.*—The fruit will now be well advanced for ripening. The leaves having been turned aside, and the fruit raised on laths placed across the wires of the trellis with its apex to the light, will be coloured well, though the absence of sun has not allowed the attainment of high colour this season, and the ripening is later than usual. If the weather continues cold and wet gentle fire heat will still be necessary to secure a circulation of air constantly, the temperature being maintained at 60° to 65° artificially at night and 5° to 10° rise by day. Cease syringing so soon as the fruit begins to be soft, and take care to have the foliage free from red spider before the syringing ceases, or the pest will increase so rapidly whilst the fruit is ripening as to seriously jeopardise future prospects. See that there is no deficiency of moisture in the borders, and, if necessary, give a thorough supply of water, mulching with some light material such as spent Mushroom-bed manure or partially decayed stable litter.

*Succession Houses.*—Do not hurry the trees during the stoning, but allow time for this exhausting process. Allow a rather free extension of

the laterals as an encouragement of root-action, but be careful not to crowd the principal foliage, and keep insect pests in check by syringing twice a day. When the fruits have stoned remove all surplus fruits, and turn the others to the light to insure their colouring well from the apex. Give thorough supplies of water through a good surface mulching of manure, and feed weakly trees with tepid liquid manure. Vigorous trees will not need more than a surface mulching, as high feeding will only cause grossness, and must be studiously avoided. Ventilate early and close in the afternoon with plenty of atmospheric moisture, so as to raise the heat up to 80° or 85°, and ventilate a little afterwards for the night, the temperature being allowed to fall to between 60° and 65°.

**Late Houses.**—Train and tie-in the young shoots that are to carry next year's crop, and allow them to extend as far as space admits, being careful to avoid overcrowding. Pinch all side shoots that are not wanted for next year's fruiting or for furnishing the trees, and any gross shoots should be stopped so as to cause an equal distribution of the sap. In thinning leave a few more than will be required for the crop. A Peach to every square foot of trellis covered by the trees is ample; Nectarines may be left a little closer. Keep the foliage clean by syringing twice a day in fine weather, and always sufficiently early to allow the foliage to become dry before night. Mulch the borders with manure, or if the trees are young and vigorous some lighter and less rich material will be better. Water thoroughly whenever necessary, always sufficient given at a time to reach the drainage. Ventilate early, and increase the ventilation with the sun heat, closing early if the ripening is to be accelerated; but if wanted late keep as cool as possible by free ventilation day and night.

Young trees in course of formation for filling their allotted space should be properly disbudded, leaving the main branches or shoots for forming them about 18 inches apart, and the bearing wood at 18 to 24 inches along them, training the extensions their full length, and pinching the side shoots on last year's wood to two or three leaves, so as to form spurs. Laterals should be pinched at the first joint, and successional growths as made.

**MELONS.**—Houses or pits in which the fruit is ripening will require a rather dry and warm condition of the atmosphere, allowing a circulation of air constantly, and the moisture at the roots should be moderated, yet if kept too dry the foliage will suffer and the prospects of a second crop seriously interfered with. When the fruit is cut clear out for another crop if the plants have fallen a prey to red spider, thoroughly cleansing the house, the woodwork with softsoapy water, the glass with water only, limewashing the walls, and removing the whole of the soil. If fermenting materials have been used for bottom heat add some fresh and mix with the top foot or 18 inches of the old material, some of the most exhausted being removed. Make firm, put in ridges or hillocks of good loam; if not calcareous add some old mortar rubbish, and if deficient of grit add road scrapings. Heavy loam will be improved by having an addition of charcoal as well as mortar rubbish and road scrapings. Tread the hillocks or ridges well down after the soil has been in a couple of days. Make the soil firm about the plants, and the balls and soil being moist no water will be needed until the roots have taken to the fresh soil. Shade from bright sun for a few days, and maintain a genial condition of the atmosphere by damping available surfaces in the morning and afternoon. Ventilate between 70° and 75°, keep through the day at 80° to 85° from sun heat, and close sufficient early to run up to 90°.

#### PLANT HOUSES.

**Callas.**—Plants that are not required to flower any longer may be hardened and planted outside. In planting them, a trench should be made and liberally enriched with manure at the base, as well as the soil to be returned again to the roots. Turn the plants out of their pots and divide them, if they have not been grown singly or an increase of the stock is needed. When planting is completed they should be left a few inches below the level of the ground, so that good soakings of water can be given during dry weather. This is all the attention needed until they are lifted in September. If sufficient stock cannot be obtained by division of the strong plants, the small suckers may be taken off and placed in small pots, grown for a time in heat, and then hardened and planted out. Care must be taken that these plants are not checked when placed out, then strong useful plants for 6-inch pots will be produced.

**Kalosanthes.**—The earliest plants will soon come into bloom under glass. A portion of the stock should be carefully hardened and stood outside where they will not be fully exposed to the sun. These will flower when those kept under glass are over, and therefore form a capital succession. Plants intended for flowering next year should not be pinched, but grown, or they will fail to flower. A clear season's growth must be allowed to accomplish this end. These should be grown in cold frames, giving them abundance of air on all favourable occasions. About the end of June they may be stood or plunged outside in a sunny sheltered position to harden and ripen their growth, and the result will be that every point will show flower the following spring. Young plants struck last autumn or this spring, and now in small pots, may be placed in 5-inch pots and pinched from time to time to insure their making bushy specimens. For ordinary decoration it is quicker and better to place four or five cuttings in each 5-inch pot, and root them together, and then allow them to flower the following season in the same pots. The shoots that fail to flower are suitable for this purpose, and may be rooted any time between now and August.

**Liliums.**—Those in houses or frames are growing rapidly, and where there are large batches of a kind grown the whole will come into flower about the same time if kept together under glass. To obviate this, the stock should be divided, and the latest hardened and plunged outside, by

which a capital succession of decorative plants will be produced. The whole of the Lancifolium section required for late flowering may be safely grown outside after this date. These plants should never suffer by an insufficient supply of water at their roots or they are certain to fail. On the other hand, they must not be saturated or they are equally liable to injury. To save labour in watering, the pots may be plunged in a light open position not fully exposed to the sun.

**Hydrangea paniculata grandiflora.**—This is a useful decorative plant in 7 and 8-inch pots, and when well grown is even more beautiful than it is when outside. If grown in the greenhouse it must occupy a light airy position fully exposed to the sun. In a shaded house or confined atmosphere it soon draws up weakly, and if it flowers will only produce very small heads of bloom. The plants do best in a light airy frame standing upon some moisture-holding material where plenty of air can be given by day and the frame closed early in the afternoon to enclose as much sun heat as possible. If the pots are full of roots, weak stimulants should be given every time water is needed.

**Isolepis gracilis.**—This is one of the most useful decorative plants that can be grown for forming a front edging in plant houses whether warm or cool. It gives but little trouble, and if divided now will remain in good condition for twelve months in the same pots. Pots 3 inches in diameter are very useful, and if some of last season's plants are divided they will make four or five each, and the remainder of the stock can do duty while these are established. The old ones can then be thrown out or broken up to replace those that have done duty in warm structures. If this is done the whole of the stock in the houses will be in good condition until next spring. They should never suffer at their roots by want of water, and two or three applications of Standen's manure during the season will do them good after their pots are full of roots.

**Scented Pelargoniums.**—The foliage and shoots of these are now largely used in a cut state for associating with flowers; in fact, many are preferred to the fronds of Ferns in rooms on account of their lasting qualities. There is no difficulty in maintaining a supply during the growing season, but for the whole of the winter and spring the plants must be provided by autumn. For this purpose numbers of the different species most in demand should now be struck and grown on in 5 and 6-inch pots, for young vigorous plants produce much finer foliage than old plants. The cuttings should be inserted singly in small pots and placed on a shelf in a warm house and shaded from strong sun.

#### THE FLOWER GARDEN AND PLEASURE GROUND.

**Selections of Bedding Plants.**—A considerable number of proprietors of gardens annually purchase the principal portion of their bedding plants, and a few hints as to which are the best in each section may prove acceptable both to them and others who may wish to add a few fresh sorts to their stock. They are given somewhat in alphabetical order, and include some in all sections of bedding plants. *Abutilon Darwinii tessellatum*, grand marbled foliage, is suitable for dotting among *Iresines*, *Violas*, and *Verbenas*, or for mixing with sub-tropical plants; *A. Thompsonii* is also suitable for this purpose, but is not so effective.

**Tuberous Begonias.**—These ought to be grown in every garden. Planted thinly among *Mesembryanthemum cordifolium* they are certain to please, and provided they are given a good soil to root in, will stand and bloom in either dry or wet weather. Nurserymen who make a speciality of them supply bulbs of good bedding sorts cheaply. *B. acotensis* and *B. weltoniensis* are both suitable for bedding out. Shrubby *Calceolarias*, *Gaines' Yellow*; *amplexicaulis*, lemon yellow; and *Sparkler*, crimson and yellow, are all effective. *Cannas* of any sort are of noble appearance, especially when planted in groups. Some of the best are *atro-purpurea*, *Chateri discolor*, *erecta*, *gigantea major*, *Henri Vilmoren*, *Maréchal Vailant*, *nigricans marginata*, *musæfolia hybrida*, *Prince Imperial*, and *picturata fastuosa*. **Chrysanthemums.**—Good early-flowering sorts for the borders are *Fred Péle*, *Hendersonii*, *La Petite Marie*, *Madame Piccol*, *Madame Desgrange*, *Mrs. Cullingford*, *Précocité*, *Scarlet Gem*, and *Mlle. Jolivat*. *Marguerites* are suitable for the flower beds, and thrive and flower abundantly in all weathers. In rather poor soil or in dry positions they are singularly effective in mixture with *Petunias*, while a few strong plants in mixed sub-tropical beds brighten these up surprisingly. *C. coronarium* and *C. frutescens* are still the best for bedding, and *Etoile d'Or* is a good yellow companion. *Coleus Verschaffeltii* is the only reliable bedder. A mass of this, planted thickly in the first instance, and surrounded with a broad band of yellow-leaved *Pelargoniums*, never fails to please. In favourable localities some of the choicer sorts may be planted out in the mixed borders.

**Dahlias.**—Any of these are effective in the back rows of mixed borders, but we will give a few of the best in each section. "Show varieties"—*Imperial*, *Condor*, *Constance*, *Earl Radnor*, *Henry Walton*, *Herbert Turner*, *Mr. Gladstone*, *James Cocker*, *Lady Wimborne*, *Miss Cannell*, *Mrs. Shirley Hibberd*, *Prince Bismarck*, *Mrs. Stancomb*, *James Vick*, *Georgiana*, *Delight*, *Canary*, *Royal Queen*, and *William Rawlings*, "Fancies"—*Alderman*, *Chorister*, *Flora Wyatt*, *Gaiety*, *Henry Glass*, *cock*, *John Forbes*, *Maid of Athens*, *Mrs. Saunders*, *Parrot*, *John Saunders*, *Mandarin*, and *Florence Stark*. "Pompons"—*Lady Blanche*, *Golden Gem*, *Little Prince*, *Rosetta*, *Fanny Weiner*, *Favourite*, *Isabel*, *Cupid*, *E. F. Junker*, *Nemesis*, *Guiding Star*, and *Royalty*. "Singles"—*Paragon*, *Acquisition*, *Terra Cotta*, *Velvet Mantle*, *Grandee*, *White Queen* or *Alba*, *Rosy Circle*, *Aurata*, *Mauve Queen Improved*, *Negress*, *Defiance*, and *Bertha*. "Cactus Dahlias"—*Constance*, *Mr. A. W. Tait*, *Picta formosissima*, *Glare of the Garden*, and *Juarezii*. "Bedders"—*Rising Sun*, *Gem of the Dwarfs*, *White Bedder*, *King of Dwarfs*, *George Thompson*, and *Alba floribunda*. **Fuchsias.**—*Golden Fleece* and *Golden Treasure* and sometimes bedded out, while any of the free-growing and free-flowering

varieties are very pretty either in groups or the centres of beds, or in mixture with other plants not commonly bedded out. *Gladioli*.—For massing *branchleyensis* and *gandavensis* are the cheapest that can be bought, and if a variety is required unnamed seedlings can be bought at a comparatively cheap rate, and will produce many fine spikes nearly or quite equal to named sorts costing double the money. *Heliotropes*.—For bedding out *Miss Nightingale* is still one of the best, and *President Garfield* is also good. *Heliotropes* are most effective when massed together in the centre of large beds, and they may be edged with any kind of *Pelargonium*. *Lobelias*.—*Brighton* and *pumila magnifica* are equally good blues; *pumila Ingrami* and *Swanley White* are the best whites, and the double *pumila grandiflora* succeeds occasionally. We only grow *pumila magnifica*, and it never fails. *Lantanas* are not much grown now; but such sorts as *La Nieve*, *Mine d'Or*, *Ne plus ultra*, *Distinction*, and *Magenta* are very pretty in mixed beds.

*Zonal Pelargoniums*.—These are the most important of all, being by far the most extensively employed. “*Golden Tricolors*.”—Mrs. Pollock, Miss Batters, Lady Cullum, and Sophie Dumaresque. “*Silver Tricolors*.”—*Porteus*, Mrs. R. B. Postans, Mrs. Laing, Lass o'Gowrie, and Prince Silverwings. “*Golden Bronze*.”—Black Douglas, Maréchal McMahon, King of the Bronze, and Golden Harry Hoyer, the last-named for edging purposes. “*Yellow-leaved*.”—Crystal Palace Gem, Creed's Seedling, and Robert Fish, the latter for edging. “*Silver variegated*.”—Flower of Spring, Mrs. J. C. Mappin, Bijou, and Princess Alexandra. Bedding Zonals.—West Brighton Gem, Vesuvius, Triomphe de Stella, Star of Fire, and Lord Gifford, scarlets; Henry Jacoby and General Outram, crimson; Master Christine and Mrs. Turner, pink; Indian Yellow; Lucius, cerise; Madame Vaucher and Niphetos, white. For hot and rather dry positions the semi-doubles, notably Guillion Mangilli, F. V. Raspaël, Lord Cecil, Madame Thibaut, and Mrs. A. Lattey are very suitable. Some of the double Ivy-leaf varieties are sometimes effective round the edges of beds, and of these the best we have tried are *Gloire d'Orleans*, Sarah Bernhardt, A. F. Barron, and Madame E. Galle. *Petunias*.—Seedlings are principally relied upon, but such good old sorts as Ashford Belle, Crimson King, Spitfire, and Purple King are sometimes preferred. *Salvias*.—The only variety extensively bedded out is *Patens*, and this lovely blue tuberous-rooted sort is grand in mixed borders or for back lines of ribbon borders. *Veronica Andersonii variegata* is not often seen, but is a very effective bedding plant, especially in mixture with *Verbena venosa*. *Verbenas*.—The old Purple King is still the best, and other good sorts are *Crimson King*, *Snowflake*, and *Firefly*. *Violas*.—These are rather superseding *Verbenas*, and if planted early in good soil are remarkably showy. *Blue Perfection*, *Favourite*, *Tory*, *Lutea grandiflora* major, and *Vestal* are all good. *Iresines*.—These must not be omitted, as they are very popular. *Herbsti* is the strongest grower, brilliantissima being a slight improvement on it. *Lindeni* is of more compact growth and richer in colour, but succeeds best on light soils.

## THE BEE-KEEPER.

### PLACING AND REMOVING SUPERS.

IN the endeavour to assist those who have bees in their care for the first time I am going to anticipate the happy day when the bee-keeper sees that the time has at last arrived to place supers on these stocks from which he does not desire to see swarms issue. It is in every case a critical period, for a little mishap, an error of judgment or mismanagement now may frustrate all the hopes of the anxious apiarian raised during the months when he has seen his stocks growing stronger and stronger, and at last showing such evident signs of want of room as to warrant an attempt at least to get them to work in supers. Few bee-keepers of little experience place their first super without some anxiety, the more especially so if they have to deal with vicious bees, which attack apparently without cause any one attempting to interfere with their affairs. Let me hope, however, that the majority will have kindly stocks, willing to endure careful handling to deal with, but in every case it is wiser until perfect confidence has been acquired to use not only a veil but gloves also, unless the operator is one of those miserable creatures who are unable to enjoy the pleasant sensation of a sting sent home by the furious efforts of an enraged insect. Confidence in himself is a great factor in making a bee-master. In all manipulations movements must be so slow and cautious as scarcely to be perceptible, the slightest hurried gesture leading to mischief. Gentleness begets gentleness, let this always be borne in mind, but many I fear seldom realise it until, roughly handling the bees, they have by them been roughly handled. It is scarcely necessary to say that this is an article for “beginners,” and in giving a detailed account of how to place and remove supers it is for their information that I am specially writing.

A stock in a straw skep is ready for a super, which may for our purpose be imagined to be an ordinary bellglass fitted with its usual appendages. Whatever kind of super is made use of makes little material difference, the method is the same. Armed with veil and gloves and a smoker the operator, if he is able to choose his own time,

goes to the hive about ten o'clock on a fine warm sunny morning when the bees will be working freely; but if, as in my own case, he is away from the apiary from early morning till evening, and so has no choice of time, he need not hesitate to place his super early in the morning, since if a stock is ready and the day proves fine possession will soon be taken of it by the numerous bees ready to work, but unable to find room in the hive. I have placed them as early as seven o'clock, and should not hesitate if driven by necessity to perform the operation at an even earlier hour. The smoker is to be taken as a matter of precaution only, for no smoke must be used unless it is absolutely necessary to resort to its use. The object is not to drive the bees down from the top of the hive where they are near the super, but rather to disturb them as little as possible. If smoke is used they will be driven down, therefore abstain from using it. I do not mean that a little smoke will prevent the bees from entering the supers, but it may delay their entrance. If the stock has been fed by the ordinary bottle feeder a zinc will be on the top hole, if not a cap or other cover; and in either case the first thing is gently to loosen the cover by passing a string or wire beneath it, taking care not to kill a bee, but drawing the string or wire through as slowly as possible, thus severing the connection which always exists between it and the hive. If this cover or zinc is now raised very slowly and cautiously scarcely a bee will rise and take wing, and the super may be placed in its position without any further action. If, however, there is a chance it is not at all an objectionable plan to bruise a few of the topmost cells—those of course containing honey—as the bees will then at once come to repair the breach and enter the super.

But it may be said that if the stock is not ready for supering nothing will induce the bees to work it. Sometimes, however, there is a difficulty—so I have heard it said—even when stocks are ready for extension, to get them to enter supers, and sections are placed in the body of the hive until they are partially worked out; but in my own apiary I have had no experience of this kind, but find that if a stock is really full of bees and brood and honey, supers are taken possession of immediately, and not deserted unless the weather is such that no honey can be collected, and in this case I at once remove all supers and give a little food each day until a “good time” comes.

There are many different materials with which supers are covered. Each one has his own; some have carpet, some one thing, some another. In my apiary anything warm and convenient is pressed into service, but the preference is given to a pad, the outside of which is made of plain calico or other cheap material, and the inside of cotton wool. These pads or cushions may be of any size, and the thicker they are the warmer they keep a glass or rack of sections. They are useful, not expensive, neat, and very warm; not a necessity, however, perhaps a luxury. Whatever the covering supers must be kept warm, and it is very rare to find one too heavily covered. The super is now placed covered snugly up, and the bees at work, and after a lapse of time, varying according to its capacity and the kind of weather experienced, it will need removal, and then a rather more formidable manipulation is necessary; in fact, sometimes it is very tedious, unless, as in the case of sections, the bees may be swept off the combs and so easily dispersed. The glass or cap with which we have to deal does not lend itself to this method, so that other means of clearing it must be devised; but when removing these supers means often suggest themselves to the mind of a thinking bee-keeper, and he may use any plan occurring to him, always taking care not to damage the comb, taint the honey, or injure the bees.

An hour or so before removing a super it is advisable to loosen it from the hive by passing a string or wire between it and the hive, as in the case of taking off the zinc or cap as before explained, and prop it up by wedges a little—an eighth of an inch is amply sufficient—from the hive, so that the bees may have a chance of licking up the honey spilt by the string or wire cutting the cells in severing the connection between the cap and the hive. When this has been done a carbolic sheet may be laid on the hole in the top of the cap, or a little smoke may be injected; and this will cause a stampede and general rush into the hive, but still many always remain. They will, however, rapidly gorge themselves with honey and be in an amicable state of mind. When all the bees which seem inclined to do so have left the cap it should be removed from the stock to some quiet shady spot, being carried with great care and inverted, and for this purpose a flower pot is a convenient receptacle to hold it in a reversed position, and the exit of the bees prevented by a board placed over its mouth. The stock can now receive another super, or if the season is very far advanced its ordinary cover; and all this time the bees in the cap will, unless the queen is with them, be driven to distraction by their imprisonment and the more ready to leave when opportunity is given them.

How shall we tell if the queen is in the super? Her presence or absence is readily ascertained by the manner of the bees, for if they

run hurriedly about seeking exit, all in a state of excitement, crossing over the combs in tremulous anxiety, her majesty is absent. If, on the other hand, the bees, ten minutes after the removal of the super from the hive, evince none of these signs of discomfort and do not seem anxious to depart, but quite at rest, the queen is there. In this case, if she cannot be caught without injury—and she very rarely can—the super must be replaced upon the stock and the attempt be made some hours after; or better still, another day, when it may please her majesty to keep within her own more proper domain and not commit the trespass of wandering from the brood nest to the honeycomb. But if her absence is ascertained the bees may now be given a chance to leave the super; but it is well to keep changing from spot to spot, as the leaving bees sometimes return with others anxious to regain their stolen store and cause an unnecessary disturbance; in fact, if not watched closely two will enter for one that leaves. A super in course of renewal must be carefully watched and guarded vigilantly from robbers often, especially when the honey flow is over, on the watch for spoils. Many bees have now left, but numbers still remain, and these may be induced to leave by gently tapping on the side of the super. I often think that preventing them from leaving for five or ten minutes at a time has a good effect, as, realising their captive position, they gladly escape when the means are given them. It is also a good plan to lay a clean white cloth over the mouth of the cap, occasionally turning the inner side out, for the bees rising to the top of the super cling to the cloth, and this being now and then turned over leaves the bees clinging to it on the outside, and these depart, while others take their place, ready in their turn to be by the moving of the cloth left outside. If they do not readily leave the cloth they may be swept off by a feather. A little perseverance in this plan will see the numbers decrease rapidly until but few remain, and these can often be ejected by a feather; but as it is far easier to get a live bee out than a dead one the greatest care is requisite, or injured by the feather, yet not killed, the timid frightened insect goes to the inmost recesses of the comb, and there, unable to move, yet desperately clinging to the comb, defies all efforts to effect its removal. Bees spoil the appearance of a super. The less frightened they are the more readily they leave. The more frightened they are the longer it takes to remove them.

There is one plan which seems to succeed with many when all others have failed; and although I have never myself had recourse to it, it seems not unlikely to be useful. It is well known that all insects are at once attracted by the light, and this may be seen by the helpless infatuation which seems to possess the moth as it flutters round the flame bent on its own destruction. So, too, with bees. If therefore the super is taken into a perfectly dark room, and the light allowed to stream in through one small opening, only the bees, they say, will leave the super and at once fly to the light and return to their hives. If there is no more convenient place a large flower pot seems to offer itself in the place of a dark room, the light being completely shut out except what comes in through the hole at the bottom. By some of these methods all supers can be cleared. If a sectional super is employed a great part of this manœuvring is unnecessary. Some advise that the sections be taken out each one, while the rack remains upon the hive. I do not, nor do I approve of this method of taking away each section as filled, but rather prefer to leave the earlier finished ones until at any rate all but the extreme outside boxes are completely sealed. Honey loses nothing by remaining on the hive, but rather gains in being thoroughly well ripened in the most natural way. Take the honey by the rack as one super in the same manner as before, except that there being no spilling occasioned by loosening the rack from the hive prior to its removal, there is no necessity to wait as in the case of the ordinary glass or cap. The propolis fastening the rack and the hive together may be severed, and the former may be at once removed to a quiet shady spot; the sections taken out each one singly, the bees swept on to a cloth, if the ground is covered with grass, and left to go home at will, or at the end of the operation they may be carried to their hive, but few will remain. In sweeping the bees from the comb care must be taken to sweep them head downwards, or they will sting and so cause inconvenience, and as each section is cleared it must be placed in a bee-proof crate, thus preventing, as I have often seen, strange bees getting on them and necessitating forcible removal, thus wasting time and energy. Unfinished sections may be returned either at once, or they may be stowed away until another rack being removed there are sufficient of these "returns" to form a rack. If, however, another rack of empty sections is to be placed as soon as the full one is removed, place the unfinished sections at the sides, and those with foundation only in them in the centre, so that the whole rack may be the more probably sealed at the same time, the outside ones being given the advantage because they are generally the last to be worked out and sealed. Does anyone now feel unable to place or take away a super? if so, I am unable to assist him further at present, but no doubt "A Lanarkshire Bee-keeper," whose opinion we all value so highly on all apicultural matters, may be able to give some useful

hints and improvements upon the methods I have enumerated, and if so I, and in all probability all others, will be glad to read what he to whom we all look as the safest guide in the management of bees, although we may differ slightly in some unessential points, has to say on the subject.—FELIX.

### EXTENDING A FRAME HIVE.

WILL you give me your advice on the following? I have a bar-frame hive with seven bars at present, five of which are sealed over. I wish to take one swarm then to get as much honey as possible in sections. Ought I to add more bars before or after swarming? and how many bars should I add at one time?—R. C.

[As you do not state the size of your frames, we cannot say positively how many more frames should be added. Our bees are at this moment occupying space equal to between 3000 and 4000 cubic inches; in fact, the measurement of the best give 3318 cubic inches for non-swarming hives, and for swarming ones 2751 cubic inches. If your hive is crowded on to the seven frames you should insert one frame of foundation in centre of combs and another outside until you have a hive of the size above. Perform this work as you observe the bees crowding towards the outside. If your bees had been occupying shallow boxes of the Stewarton type it would be more natural for the bees and easier for you to add a division at a time. Two hives  $15\frac{1}{2}$  square by 9 inches deep is a good size for either swarming or non-swarming hives. We would advise you in an uncertain year like this, to work your hive on the non-swarming principle, then immediately after the honey season is past make an artificial swarm or more and feed up to the necessary weight, having the bees in full-sized hives with young queens at their head. This plan will give the best return this season and put you on the best footing for next year.]

### HIVES WITH FRAMES ACROSS OR PARALLEL TO THE ENTRANCE.

I FREQUENTLY see the practice of having the bar-frames parallel with the entrance condemned. I shall be glad if you would give the reason, as I have one. A friend of mine, who has kept bees for about ten years, has one or two hives made on this principle, and he has quite as good results from them as from the others, and he cannot see why they should be condemned. Bees do not always build their combs at right angles to the entrance, as he has a skep, which I have seen, in which the combs are nearly parallel with the entrance.

I saw lately that when you take the frames out of a hive you always ought to take out an even number. I shall be glad if you will explain this as well.—H. T. S., *Lincoln*.

[Our reasons for the condemnation are many. The principal one, however, is judging by results. When we see a number of hives managed on two different principles, standing side by side, receiving the same treatment, and the bees in those having their frames across the entrance dead, while the others are alive and extra strong, as we have often observed, and particularly this year, we may safely conjecture that having the frames so placed is the cause of the mortality. But it would not be fair to condemn on that alone without being able to give other reasons.

The argument that bees do not always build their combs at right angles to the entrance does not support the theory; neither is the argument of having good results from those having their combs parallel to the entrance. Results of that sort go by degrees. The locality may be good enough for a hive, if properly managed, to yield to its owner 400 lbs. of honey, and yet he may only be able to get, say, 20 lbs., and this low yield might be called "good results." This is by no means uncommon. Then it must be remembered that bees in a hive are not there according to nature. Bees in a state of nature, as a rule, have their combs suspended, for instance from a shelving rock thoroughly protected from above, but from the sides or beneath the space is open for ventilation. When they take up their abode in trees they are similarly protected, having always breathing space beneath. When bees take up their abode in a hive, and left to themselves, they incline to twist their combs, and, as a rule, the ends of the combs are twisted towards the entrance in nine cases out of ten, and the twisted combs is Nature's adaptation towards a comfortable breeding place. But our bees are not in Nature's keeping.

If you select a room having one doorway and no other outlet, fill the room with partitions open at the bottom similar to the combs of the bees, you will be unable to crowd animal life into these spaces, but you can try the experiment with them both ways. With the ends of the combs to the entrance you will find the current of air enter some of these, and return by others. The bees can regulate this to a great extent, drawing in the fresh and expelling the vitiated air, and may be able to alter the course, but a strong hive will expel the vitiated air before it condenses on any part of the hive, and the hive has always a good circulation of air. The combs placed across the entrance, the current of air may be either almost still or extra strong, depending a great deal on the doorway. Having the combs across the entrance the perspiration of the bees between the combs strikes the wall opposite, and condenses thereon. Now, a bee can suffer a number of degrees of frost in a dry atmosphere, and although it be chilled, it will in gentle heat revive and fly about, but a bee coming in contact with damp at a temperature much above freezing dies instantly—the reason I advocate ventilating floors. Hives with frames across the entrance are termed warm hives, the reason I condemn them. The interior at times during winter becomes in a measure suffocating to the

bees, they fly ont, and are very often lost. They are liable to damp internally, therefore is more fatal to bee life than an airy hive. If I mistake not this was the objection the late Mr. T. W. Woodbury had to hives having their frames across the entrance, and his opinions were entitled to respect. A bee leaving its hive during winter will return much quicker if its frames are at right angles to the entrance than if they were across, because in the former case it is in a better sanitary condition than the other, and leaves their combs right at the entrance in a cleanly state. Not so with the others, where they have to creep along a dirty floor, the *débris* in which adheres to the bees, and they must rid themselves of this before they will return to their hive. When the frames are placed across the entrance the pollen is stored in the front combs, and in this position is destroyed during winter, and if used by the bees is almost sure to start bacilli to activity, which are liable to create dysentery and foul brood. Supering cannot be carried out so successfully with hives having their frames across the entrance as with those at right angles; in fact, I do not know one redeeming quality in having the frames across the entrance. They may succeed in some climates or localities, but in ours they will not. Preserving bees from May till May is the secret of profitable bee-keeping, and that should be done without a single manipulation from September till May.

Your second query we cannot answer without having full cognisance of the article referred to.—LANARKSHIRE BEE-KEEPER.]

### INCITING ROBBERS.

In your paper of May 13th, page 389, your correspondent, "A Lanarkshire Bee-keeper," says "Endeavour to keep down every scent of honey, syrup, or combs that is likely to attract bees, which incites robbers, and may spread disease."

A few days ago I was watching my bees as they flew in and out. I saw a considerable commotion at the entrance, and on looking closer I found fighting going on, and I felt sure something was wrong inside.

The hive is provided with two moveable shallow drawers placed at the bottom, and to draw out behind. The top one has a perforated zinc bottom, and serves the purpose of a floorboard, while the lower one is filled with dry peat moss. I drew out the lower drawer and found in one place a quantity of honey, and a good deal of broken comb in bits. This had all come from above. I fancied the robbers had got in and were doing much mischief. There were numbers of dead bees outside, and I expected to see many inside. I opened the hive, which was a frame one. I found a comb with a good deal of mouldy bee bread in it, while the surrounding cells were filled with honey. There was not a single dead bee on the floor, and the bees were busy pulling out the mouldy bee bread, and in doing this they had broken the cell sides, allowing the honey to fall down below. I helped the bees by removing the bee bread. I washed the perforated zinc, and put clean peat moss below, replaced the frame, and shut up the hive. Had this robbing been allowed to go on, increasing numbers of bees would have attempted to get in, and the result would have been very serious. Fortunately it was seen in time, and in twenty four hours the attempts to rob ceased altogether. There was no longer any smell of honey to tempt stranger bees.—A BEE-KEEPER.

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

*Monarda didyma* (A. J. L.).—Plants can be purchased at a moderate price from any nurseryman who makes a speciality of hardy plants.

*Peaches Falling* (Rugby).—You do not say when the trees were removed. If the root-action is not defective, or the crop too heavy, we can only attribute the evil to defective fertilisation. Are you certain that the border is not dry at the bottom? and are you certain also that you have not been syringing too late in the afternoon and keeping the house closed too long in the morning? There is a mistake somewhere, but we cannot precisely indicate it from your description.

*Mites in Garden* (H. J. B.).—Your garden is infested with a species of millipede (*Julus*), which feeds on decaying matter, and is injurious to bulbs

and the roots of plants. A good liming when the ground is vacant would do good, and an application of lime water now would not do harm. You might also try the solution advised in reply to another correspondent.

*Auriculas* (J. L.).—Occasionally a plantlet will form on a flower stem. If you wish to establish the plant you cannot do better than carry out your suggestion of bending down the stem and pegging the growing part into a pot of sandy loam in a shady position, and if the soil be kept moist you will probably succeed in your object.

*Flowers for Market* (Blackwing).—We cannot advise anyone what particular flowers to grow for profit, as obviously so much depends on the soil, district, and local demand. Violets, Narcissi, Anemones, Wallflowers, Pinks, Carnations, Roses, Dahlias, Chrysanthemums, and Christmas Roses are found profitable by some cultivators in places where the plants grow well, and where there is no difficulty in disposing of the flowers.

*Weed-infested Ground* (A. F. Southport).—Your land is infested with one of the Equisetums, which is extremely troublesome when established. Its presence suggests that the soil needs draining, this with heavy applications of lime and hoeing regularly before the growths were half an inch above ground, having extirpated it from a field that was overrun with this pernicious weed.

*Caterpillars on Vines* (J. C.).—Your letter has arrived too late to permit of a close examination of the caterpillars at once. They are injurious. Try the mixture recommended to another correspondent for destroying grubs, reducing the petroleum, however, one-half and adding two ounces of quassia chips to the solution, strain through muslin and syringe the Vines soon enough in the evening to get dry before nightfall. If wet when the sun reaches them in the morning the leaves might be scorched.

*Maggots in Strawberry Beds* (W. E. B.).—The maggots shall be examined; in the meantime you might try the effect of a mixture of hellebore and petroleum in soapsuds. Dissolve 2 ozs. of soft soap and a little soda in 2 gallons of soft boiling water, also 2 ozs. of white hellebore powder, stirring in while still hot a wineglassful of petroleum, and try the effect of this on a small plot of ground or a few plants.

*Red Spider on Vines* (Merchant).—Are you sure it is the red spider that is attacking your Vines? It does not usually spread so soon in a moist atmosphere, and when the Vines are well supplied with water. We almost wish you had sent samples of the infested leaves. You may sulphur the pipes as you suggest, but we are by no means certain it will have the desired effect. We suspect you are keeping the house rather too close. Leave the top ventilators open half an inch or so all night, and increase the ventilation as soon as the temperature commences rising in the morning.

*Alternantheras* (Idem).—Take care your *Alternantheras* are well prepared; do not plant until the weather is quite warm, even if you wait till the middle of June; arrange so that the leaves nearly touch each other when the plants are placed in the beds, and give them warm water to start the plants into growth.

*Worms in Rose House—Mulching* (Puzzled).—The worms are not so injurious to Roses planted out as they are to those in pots, through their choking the drainage. The soil must be in a very moist state, air not entering freely by the surface. The worms may be brought to the surface, and they can then be cleared away by watering with a solution of corrosive sublimate at the rate of half an ounce dissolved in fifteen gallons of water. They must be kept from fowls, otherwise they will be poisoned. It would be preferable to remove most of the cow manure, and giving a dressing of quicklime, a peck per rod being sufficient, pointed in with a fork. This will do something to extirpate the worms, and greatly improve the soil by setting air into it.

*Management of Fruit Trees* (H. P.).—We cannot remember the page from which the citation was made—"close-prune spring growth, but only shorten midsummer growth." Our correspondent "J. E." can possibly do so, and we have no objection to publishing the information. The writer of that sentence has grown fruit trees that so far as we know have not been excelled for size, form, and productiveness by any others of the same age in the kingdom.

*Sowing Exhibition Peas* (A Beginner).—Sown at this time of year, Peas require about fourteen weeks, more or less according to the variety and the weather experienced, to come to perfection. By this it will be seen you must sow at once and not depend on a late sort, or the pods will not be fit to gather by the middle of August. *Ne Pins Ultra* is one of the best for late shows, but this you would not have time to grow, and your best plan will be to sow either *Telegraph* or *Stratagem*, giving these liberal treatment in the way of mulchings and waterings in order to keep them vigorous and free from mildew, to which they are very liable when sown so late in the season. The Dwarf Beans should be sown about eleven weeks before they are wanted, consequently these also should be sown at once. Both these and the Peas will germinate more quickly if soaked in water during the night prior to sowing.

*Constructing Glass Houses* (Constant Reader).—It would be preferable to have glass in front, the front wall being taken up 18 inches to 2 feet, and 2 feet 6 inches of front lights, and made to open the entire length of each house separately. The back wall for a lean-to house 12 feet wide will need to be, the front being 4 feet or 4 feet 6 inches, not less than 12 feet high, so as to allow of a proper pitch for the roof. We cannot undertake to get out quantities and give estimates of cost, but any horticultural builder would be pleased to give you a specification and estimate upon your sending a sketch and stating your requirements. The houses would no doubt be very useful, but without pits and frames they would be inadequate for a kitchen garden of four acres. Some pits and frames would be far more useful than the houses "for raising young stuff for the kitchen garden and bedding plants," and would not cost nearly so much money. The piping you have shown would be quite sufficient, but before anything is done it should be decided what the structures are really intended for, which we cannot learn from the data given.

*Vines Mildewed* (The Rev. G. S.).—The leaves enclosed to us are badly infested with mildew. There is no better remedy than dusting thoroughly with

flowers of sulphur in every part, the under as well as the upper side of the leaves, and repeating as necessary. Admit air more freely, especially in the early part of the day. It would be advantageous to apply a dressing to the border of two parts quicklime, one part dry wood ashes, and one part soot, thoroughly mixing, and applying to the border at the rate of a peck per rod (30½ square yards), and merely point it in with a fork. This may be repeated in about six weeks, and again in a similar period, but not after the Grapes begin to change colour for ripening,

**Plants for Stone Vases on Lawn (Aurora).**—You will find few better plants for the vases than *Yucca recurva*, its fine green foliage, beautifully recurring, and noble aspect, rendering it a striking object. It is hardy in all but very wet soils. Being in a vase well drained it would make thoroughly solidified growths, and no doubt prove perfectly hardy. *Eryngium pandanifolium* is a noble plant well suited for vases, having leaves about 3 feet in length, the flower stem rising to a height of sometimes 10 feet, bearing candelabra-like branching flower heads of a reddish violet colour. It also is hardy in well drained vases. *Chamaerops Fortunei* is also quite hardy and makes a charming vase plant. One of the most graceful plants for vases is *Arundinaria Falconeri*, it requires abundant supplies of water in summer. *Aralia Sieboldi* is also very useful, and it succeeds admirably with a little protection in severe weather. All the *Acanthuses* are stately in growth, having leathery and beautiful foliage and numerous flower spikes in summer. The best are longifolia, hybridus, candelabrum, and spinosissimus. Of plants that require protection from frost in winter the *Agaves* are very fine, particularly *A. americana*, and its variegated variety, *A. americana variegata*. *Agapanthus umbellatus* is good; it is hardy on rockwork, and would, no doubt, prove equally so in vases. Any of the plants could, of course, be grown in pots of suitable size for the vases, and plunged in them in summer, wintering in a greenhouse those of doubtful hardiness.

**Vine Leaves Scorched (Subscriber).**—The leaves are discoloured through the evaporation being in excess of the power of the roots to absorb moisture, and in consequence the tissues shrink and scorch. This is very common after a period of dull weather, when the tissues are thin and full of moisture, the change to bright weather find them unprepared for the change, and the leaves transpire more moisture than the roots transmit to them. The proper thing to do would be to shade, but this is inconvenient in the case of vineries, so the next best thing, and the one that finds most favour with growers, is to admit air very carefully in such weather, commencing early—just a little to cause a circulation, and increase it gradually with the advancing temperature, and so have the leaves dry before the sun acts powerfully upon them. Evaporation is thereby progressive, and the roots seconding the demand for nutriment are brought into comparatively increased action, and so are capable of meeting the demand when steady; but when air is not given until the temperature is high and the sun powerful, the evaporation is so great and sudden that the roots are unable to respond to the call made upon them, and in consequence the tissues of the leaves are dried up. Earlier ventilation and more moisture in the atmosphere obtained by damping available surfaces other than the foliage two or three times in the early part of the day, so as to keep the house cool, would probably have prevented the mischief. Indeed, early ventilation would have been all that is necessary to prevent the condition your Vine leaves exhibit. More and early air-giving ensure stouter textured leaves that are the least liable to be scorched.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*C. H. S.*)—We do not undertake to name varieties of florists' flowers, and such the vast majority of Roses are, but only species; and all we can say is the imperfect flower you have sent resembles *Isabella Sprunt*. (*H. K. V.*)—*Farugium grande*. It requires liberal supplies of water during summer. (*T. R.*)—*Narcissus poeticus flore-pleno*. (*Reader*).—1, *Galium verum*; 2, *Alliaria officinalis*. (*Nac*).—1, *Hedysarum coronarium*; 2, *Pulmonaria officinalis*; 3, *Alyssum saxatile*; 4, *Doronicum pardalianches*; 5, *Caltha palustris flore-pleno*; 6, *Fritillaria Meleagris*.

#### THE FUTURE OF FARMING.

SINCE writing our last article we have had to inspect and make a valuation of some property which has recently fallen in to an estate under our care. Of this property one farm was to us an object of curiosity and interest, from the fact its having been in the hands of the tenant for twenty years, and during the whole of the time it had been farmed strictly according to the four-course shift. Finding the depression press heavily upon him, the tenant after due consideration of ways and means came to the conclusion that the only remedy was a reduction of the rent of the farm to 10s. an acre. At the time of making this demand his landlord was old and in failing health, so the reduction was granted by him in order to avoid trouble. We mention this case as showing what in the opinion of the ordinary tenant farmer is the proper remedy for the agricultural depression—a sacrifice by the landlord of fifty to sixty per cent. of his income. So far as the farmer was concerned he had only to obtain this enormous concession and to keep on farming strictly on the old lines, which in his opinion were not capable of improvement. After careful inspection we had to report clean land, tolerably well drained, with crops of an uniform degree of medium excellence, the usual proportion of Wheat, Barley, Beans, Peas, a few Oats, a layer of Clover, another of Trefoil, a Mangold field, a field held in reserve for Swedes and White Turnips, and the inevitable long fallow.

Now in common fairness we are bound to inquire if this is all that is possible for the future of farming; nay, we may claim to have shown already that it is possible for the farmer to do much more with the land than he has hitherto managed to do. But he cannot do so unless he confines his efforts well within the scope of his means. He must rather ascertain how much he may put into the land with advantage than how little. The weak points in this particular farm were the small proportion of grass to arable land, no sheep, long fallows, ordinary cultivation generally. Grass land, to begin with, involves very little labour either with men or horses,

and it may certainly be said of ordinary grass land that the returns are proportionate. Yet we have never seen an ordinary meadow that was not capable of improvement, and we have had to deal with much poor grass land in our own practice. Here is a case in point. Some fifteen years ago we had to divide a park into two parts with a wire fence—one part to be kept for hay and grazing, and the other only for grazing. Now the whole of this pasture was very poor, yet annual dressings of manure soon effected an improvement in the hay pasture, the hay crop being generally good, and the aftermath abundant. At first farmyard manure was used, then came the manure dealers' special mixture of artificial manure, affording results about equal to those obtained by the use of farmyard manure; this was followed by Professor Jamieson's mixture, each sort of manure being obtained separately and the mixing done at the farm, and it was owing to the remarkable effect of this home-mixed manure upon this as well as other pastures that we first called attention to it in these articles. Subsequent results were even more satisfactory, for there was an annual improvement in the hay crop, and last year the crop was fully twice as much in bulk as it had ever been before. The contrast between the hay pasture and that devoted altogether to grazing was remarkable; the one yielding heavy crops of hay, an aftermath for cows till October, and grazing for sheep till the middle of February, the other a tolerably abundant supply of food for cattle and sheep in summer and early autumn, but the growth was always late in spring, and at the best in summer it was altogether inferior to the hay grass, simply because it had no manure but the excrement of the animals grazing upon it.

The subject is so important that we must give another example before leaving it. By careful selection of seed and high cultivation of the land Mr. Faunce de Laune has made new permanent pasture so productive that it will carry ten sheep to an acre. Let us see what this means. Taking the wool at 6 lbs. per fleece we have:—

60 lbs. at 10d. .. .. .	£	s.	d.
Ten sheep at 50s. .. .. .	25	0	0
	27	10	0
Per contra—Rent and taxes .. .. .	2	5	0
Manure .. .. .	1	3	0
Labour .. .. .	1	0	0
	4	8	0
Balance .. .. .	£23	2	0

From this heavy balance we should have to deduct the value of the sheep at the beginning of the year and allow a slight margin for probable losses, but we should then be able to show a very satisfactory balance-sheet, even if we had to make a farther deduction for dry food, against which, however, we ought to be able to show a higher return than 50s. per head for well-bred sheep. We do not forget that many a farmer will say that his land is too wet to carry sheep in winter. In point of fact we have a farm in hand of some 330 acres where this proves to be the case; but we do not despair of making the land so sound by drains and careful cultivation as to be able to keep a flock there.

No doubt the laying down land to permanent pasture cannot be undertaken upon a large scale by farmers generally, but all risk could be avoided by doing a few acres year by year till the farm had its fair proportion of grass land. It is because the work is undertaken by incompetent men that results so frequently prove unsatisfactory. To the use of pure seed carefully selected, and judicious cultivation, we must add subsequent management of the pasture, for without it failure is inevitable. With enough sound pasture we are able then to have our flock at hand for folding purposes upon any of the arable land crops where folding is desirable to impart a fresh store of fertility to the soil, and instead of leaving bare fallows for the whole of the summer let us get them clean early in the year, and either

sow roots or green crops for ploughing in, and so turn the land to account either to provide a store of cattle food for winter or to lay up a store of fertility in itself for the future.

(To be continued.)

#### WORK ON THE HOME FARM.

Swede sowing has been done for the main crop, and the soil has been prepared in two ways for the seed. Where Rye had been eaten off by sheep in folds the land was ploughed, broken up by heavy harrows, bearing in this locality the name of duck's foot harrows; a heavy roller was then used to crush the soil, home-mixed chemical manure sown, light harrows passed twice over the field and the seed drilled at the rate of 3 lbs. an acre. Bastard fallow land had furrows made with double-breasted ploughs, farmyard and chemical manure applied, and the land ridged precisely as if for Mangolds. The chemical manure used per acre is three-quarters cwt. nitrate of potash, half cwt. nitrate of soda, and 2½ cwt. steamed bone flour, 2½ cwt. ground coprolite, procured separately and mixed at the farm a few days before being used. Coprolite is invariably received in an excellent condition of fineness, but we have had some difficulty about bone flour. We, however, were so fortunate as to procure our supplies from a manure company whose manager is an intelligent man and clever chemist; and upon it being explained to him that it is the minute division of the particles of steamed bone flour that imparts a special value to it, he at once offered to supply us as per sample at an additional charge of 5s. per ton for extra grinding, and we were quite willing to pay so reasonable a demand. Every effort is being made to keep down weeds in corn crops, especially Thistles and Charlock. Winter Tares, too, have had the hoes passed between the rows to cut down a heavy crop of Thistles. The Tares are now growing freely, and this useful crop will be quite ready for the ewes and lambs when they come off the Rye Grass. Wet weather set in just as they began the Rye Grass, and they did not make clean work of it for a few days. There was, however, no falling off in condition, for they had plenty of lamb food, and Mangolds with the Rye Grass. This sound wholesome food checked any tendency to scour, and glad are we to say that flock is clean, healthy and almost free from foot rot. We never allow a flock affected by foot rot to go near a sound flock, for this troublesome complaint is so infectious that it can hardly ever be entirely got rid of. The ploughs are following the folds closely upon the Rye Grass, as we are anxious to have another green crop ready by August for early tugging. To have a crop of early lambs the tups must be with the flock quite by the second week in August, and the ewes must be well fed and in good condition then to insure success. Stick to the sheep, say we again and again. Do not be frightened by reports about importations from the Colonies; depend upon it there is still "money" in sheep-keeping, and "golden hoofs" still leave their mark upon the land.

SEEDS AT EDINBURGH AND LIVERPOOL.—At the Liverpool International Exhibition and at Edinburgh Messrs. Sutton & Sons, Reading, are represented by an attractive display setting forth the several branches of their business. The upper portion of the stand, divided into seven equal sections, is arranged in a most artistic fashion. The centre is occupied by a collection of models of agricultural roots from nature, representing all the leading varieties of Messrs. Sutton's introductions during the past thirty years, while the sections on either side are taken up by specimens of special export boxes of seeds, illustrating the new process invented by the Reading firm. Arranged in glass cases immediately below the seven sections just alluded to are some beautiful models of various vegetables, fruits, &c., executed at Reading from real specimens; while beneath these is the collection of natural grasses.

#### REMARKS.

16th.—Wet day, but cleared up towards evening.  
17th.—Wet till 10 A.M.; generally dull afterwards.  
18th.—Fine, bright, and pleasant, with southerly gale.  
19th.—Dull early, and wet till noon.  
20th.—Warm and dull, with heavy showers between 1 and 2 P.M.; fine after.  
21st.—Very fine day, with dull evening.  
22nd.—Sharp thunderstorm in W. from 3.45 to 4.45 A.M. Very heavy rain from 4.8 to 4.10 A.M., 0.12 inch falling in those two minutes. Rather oppressive all day.  
Warmer than last week and rain again above the average. Much dull weather has kept the range of temperature less than usual at this season.—G. J. SYMONS.

### GROUPS OF PLANTS.

#### FERNS AND ORCHIDS.

**L**ARGE specimen plants of all kinds do not seem to be increasing in numbers for exhibition, and many provincial societies now find it difficult to secure a good competition in such classes. For some time the demand has been increasing for small or medium-size plants that can be conveniently and quickly grown in ordinary houses, and which can be usefully employed in decoration. The giant specimens that were such favourites at one time are still admired as examples of cultural skill, but it is only in a few establishments that the requisite time and labour can be devoted to them. They occupy considerable space and usually require houses specially appropriated to them, and except in large conservatories or winter gardens where they can be allowed plenty of room, they have a crowded appearance that is far from pleasing. Small plants, on the other hand, are useful for many purposes. They can be had in large numbers and great variety, and they can be inspected in their houses with some satisfaction. The greater demand for the decoration of rooms with plants, and the large quantities of flowers needed for cutting, have also had some effect upon this alteration of taste, but it is an undoubted fact that the popularity of large specimen plants is declining.

This has been recognised by the majority of horticultural societies, and one result has been that more classes have been devoted to groups at the principal shows throughout the country. At some exhibitions, tastefully arranged collections of plants now constitute the chief attraction, where a few years ago the competition was confined to two or three exhibitors, or there was no class specially provided for them. This advance must be regarded as a decided improvement, for such classes are advantageous in many ways. They enable a greater number of gardeners or amateurs to compete, they permit the exhibitors to show at the same time their skill in cultivation and their taste in arrangement, and they form a most effective portion of any exhibition. At the chief provincial displays like those at York and Manchester such groups are invariably admired by the visitors as much as, and sometimes more than, any other part of the show; they are less tiring than the long formal rows of plants on stages or the boxes of cut blooms frequently presented to the public. There is another point which serves to render groups popular with exhibitors, and that is the cost of carriage is much less than for the huge plants entered in what are termed "the great prize classes," for sufficient plants for an ordinary sized group can be packed in a cart or small van. It is not, therefore, surprising that with all these points in their favour groups of plants have received more encouragement at exhibitions of late years.

It is usually stipulated that groups in competition should comprise flowering and fine-foliage plants, the proportion of each being left to the taste of the exhibitor; in a few cases, however, classes have been provided for foliage plants alone

No. 310.—VOL. XII., THIRD SERIES.

with excellent results. This can be done with the best effect at large shows where adequate encouragement can be given to flowering plants as well, as otherwise the general appearance of an exhibition would not be sufficiently bright, but with a due proportion of floral colours a few groups of foliage plants are most refreshing, and serve as an admirable foil to the brighter hues. One of the best innovations of this kind is that which has become popular with some exhibitors at the Brighton and other shows on the south coast—namely, groups of Ferns arranged for effect. The experiment proved very successful and gave immense satisfaction to all the visitors, for several cultivators admirably proved what beautiful displays can be provided by employing such plants alone. In habit, form of fronds, and shade of green, the Ferns are extremely varied; and by the exercise of some little taste in forming an undulating surface to work upon, with a few mounds to increase the diversity and a careful choice of material, a group of Ferns can be rendered a charming addition to any floral gathering.

Quite recently another form of grouping has attracted attention and is one that is likely to advance very rapidly in public favour, and that is the arrangement of Orchids with Ferns. The cultivators of Orchids have increased considerably in the last ten years, and much larger numbers of these plants are now grown than has ever been the case before. It is quite reasonable, therefore, that they should have due provision made for them at exhibitions. This has been done for some time by forming classes for a certain number of specimens, prizes of substantial value being usually offered, but this has been found to be insufficient. Those amateurs or others who possess large plants can command the prizes at will, and the number of competitors is correspondingly diminished. In addition to prizes for the "specimens," it has been found that the best way to increase the number of exhibitors is to give those a chance of success who have only small plants to contribute, and who would on that account be deterred from entering the ordinary classes. To meet this difficulty several societies have offered prizes for groups of Orchids arranged for effect with Ferns and Palms, and the results so far have been highly encouraging. At Birmingham a beautiful effect was produced by the judicious employment of foliage plants, chiefly Ferns. At the Crystal Palace recently several pretty groups were arranged in a similar way; and the Royal Horticultural Society is offering prizes at the Liverpool Show which may be expected to bring an equally satisfactory competition. Orchids are admirably adapted for grouping. The majority are extremely graceful, they are varied in forms and colours, and altogether they are scarcely equalled by any other flowering plants for this purpose. The London nurserymen have repeatedly proved the truth of this in their displays of Orchids, and it is recognised and acted upon in every amateur's collection of Orchids. Plants of medium size can be much more effectively employed in such groups than the large specimens, and thus all growers can compete with a prospect of success depending chiefly upon their taste in arrangement.

Many other provincial and local societies might well give attention to this matter, as by providing classes for groups of Ferns or Orchids, or a combination of the two, they are not likely to lessen the interest of any other portion of their show, and they may add features of much beauty and importance. —L. C.

#### TOMATO CULTURE IN THE OPEN AIR.

THERE is no more popular vegetable at the present time than the Tomato. Not many years ago its culture was wholly confined to glass houses and large gardens. I can remember a rough red variety being grown in a duke's garden a quarter of a century ago, and I do not think it was to be found in another part of that county; but now they are to be found in almost every parish, and as fine crops are often produced by a keen amateur or enthusiastic cottager as in the largest of gardens. It is not often we hear of the Tomato by the name of Love Apple now. When

No. 1966.—VOL. LXXIV., OLD SERIES

it was grown chiefly for ornament this was a very appropriate name, but now when they are eagerly consumed uncooked as a salad and cooked in many ways pet names are dropped, and they are regarded as a commercial commodity of great value. It is astonishing the price they command in the market. We never knew them to be less than 6d. per lb., and we have seen them at 3s. and 4s. per lb. Their culture would, I am sure, pay equally as well as Tobacco or any other crop, and I am rather surprised that small garden owners have not turned their attention to growing them for profit. If they pay anyone to grow them under glass early in the season at 2s., 3s., or 4s. per lb., they would pay equally well or better at 6d. per lb. from the open throughout the autumn. Were I a grower of plants for sale I would advertise young Tomato plants by the thousand at this season. There are many who would gladly grow them, but raising the plants to have them a good size at this time is a matter they cannot accomplish without the aid of glass.

One year I had a quantity of Tomato plants left over. I advertised these and they were all sold in less than a week, which indicated to me how anxious many were to secure plants ready for putting out and grow Tomatoes. Carter's Green Gage is a yellow-fruited variety. It bears heavily and does exceedingly well in the open. Indeed it never fails to produce a satisfactory crop, and it is a great favourite with all who have grown it. Shy-fruited varieties should never be tried in the open. Laxton's open air variety is also excellent and is a sure bearer of useful fruit. One of the main points to insure success is to have good plants to begin with. The first week in June is an excellent time to plant, and if the plants are 18 inches or 20 inches high then, well hardened off and robust, there is not the slightest danger of the crop failing. Such plants would be in bloom before June was out, and they would begin ripening fruit in August, and continue bearing until frost cut them down. We always grow a quantity of early Tomatoes under glass, but from August onwards we depend wholly on our open-air plants, and we have never been disappointed. They must have a good position. They will not succeed in the shade. A warm sunny aspect suits them admirably. We have often seen them do well as standard plants tied to stakes in warm spots, but if the shelter and support of a wall or wood fence can be given them they will be all the better for it. We put a plant here and there on our kitchen garden fruit wall wherever we can find space; but some of the cottagers and farmers in our district who have no walls round their gardens put a few out on the front of their houses or against any fence that may be there, and the results are always encouraging. Experienced cultivators often grow them well in very poor soil, as they secure dwarf short-jointed plants in this and feed them well with liquid manure after the crop is formed; but the inexperienced will find their plants do best by giving them rich soil and getting them to make robust growth, which will bear fruit freely without more attention than restricting the growths and tying in the shoots. Each plant should have one barrowload or more of good soil placed at the roots, and in planting the roots should be put well down, as many roots are sent forth from the stem, and when part of this is buried it increases the feeders. Should the plants be somewhat delicate at first they should be protected for a few nights when first put out, and as soon as they begin growing select two of the most promising growths, tie them in or nail them up as leaders and pinch off every other shoot. This is very important, as when the plants form a mass of shoots they never fruit well. Throughout the whole of the period of their growth they should be examined at least once a week to remove the side shoots and tie in the two leaders. Where there is plenty of space the plant may be allowed to take the form of a fan-shaped tree, but avoid crowding by all means, and where a heavy crop and good returns are the only consideration we would adopt the restricted system of growth.

Ordinary plants will begin to fruit at 2 feet from the ground, and they will produce closely formed clusters all the way up afterwards. When a large quantity of fruit has been formed liquid manure should be given two or three times weekly, and this may be applied as long as the weather is warm and the fruit is swelling freely. There is another good way of treating the plants before planting them out. This is to pot them into 6 inch or 8 inch pots, allow them to make a good leading shoot or two, which should be tied to a stake, and they will form a quantity of fruit before they are 3 feet in height. They are well treated under glass until about the middle of June, when they are planted out with the fruit attached and as this swells up and ripens early fresh quantities are produced in rapid succession. This is an excellent plan to adopt in cold districts where open-air plants would not be likely to succeed until midsummer or later.—A KITCHEN GARDENER.

So rapidly has the acquired taste for Tomatoes increased during the last few years, that in order to meet the great demand for this wholesome vegetable-fruit its cultivation has been considerably extended in both private and market gardens. As we grow Tomatoes somewhat largely, and I think I may say successfully, and as our mode of treatment is somewhat different from that practised by many, a few remarks may be acceptable. Instead of placing out plants from 9 to 12 inches high, as most growers are accustomed to do towards the end of May or early in June, we place large well established plants which have been grown for that purpose in pots ranging from 7 to 9 inches in diameter. We also utilise the best of the plants which have ripened their crops of fruit in the forcing houses in May after they have been properly hardened, as the larger the plants are at planting out time the sooner will they yield gatherings of fruit. Frequently our plants have set their fruits before they are planted out, thereby ensuring far greater supplies of fruit being gathered from plants growing out of doors than could otherwise be secured. This is a most important detail to be observed. The most suitable aspects for Tomato plants to occupy are south and west walls or fences. They may also be grown, but not successfully, against an east wall or fence.

**PLANTING.**—Assuming that the soil is moist at the roots, turn the plants out of the pots, removing the drainage, and in the event of the roots being matted round the soil, as is sure to be the case with plants which have been forced, loosen them a little round the outside with a pointed stick before planting. Prepare a soil consisting of three parts of light loam and one of short dung well mixed, pressing it firmly about the balls of earth and roots. This being done, secure the shoots at 9 or 10 inches to the wall or fence with nails and shreds, allowing sufficient room in the latter for the development of the individual shoots. Single-stemmed plants should be planted at the same distance apart as that recommended for the shoots on the wall. Then give sufficient water at the roots to settle the soil about them, and in the event of bright sunshine prevailing at the time, hang mats over the plants for a few days until the roots have pushed into the new soil. After which, the more sun the plants are exposed to the more fruit they will bear, if their treatment be good.

**THINNING AND STOPPING SHOOTS AND LEAVES.**—Upon the manner in which this operation is carried out depends success or failure, as anything approaching overcrowding of the shoots and leaves will assuredly lead to the latter. Therefore all lateral growths should be pinched at one joint and the compound leaves at two or three joints from their bases, so as to prevent both shoots and leaves touching one another, as well as to expose the fruit to the full influence of the sun. The secondary growths should be stopped at one joint above each cluster of fruit. The slight check thus given to the flow of sap will cause the fruit to set more quickly and better than would otherwise be the case. If fine large fruits are desired in preference to medium-sized ones the clusters should be thinned, leaving, of course, the best-shaped and most even fruits for the crop.

**WATERING.**—Although Tomato plants, when treated as indicated above, yield the best possible results out of doors during a hot summer, it must not therefore be assumed that they like to be kept dry at the roots, the case being quite the reverse of this, and the plants swelling their fruit will be greatly benefited by an occasional soaking of liquid manure. A warm and somewhat dry atmosphere is most congenial to the requirements of the Tomato. There need be no apprehension of plants growing under the favourable conditions set forth above being attacked by the Tomato disease, which, in my opinion, is the result of the conditions under which the plants have been grown—viz., a cool humid atmosphere and an overcrowding of shoots and leaves, the latter being the most potent factor of disease—a disease which in the case of plants grown under glass and against sunny walls out of doors is quite avoidable in both cases, though if the summer should be a wet and cold one, the plants out of doors would very likely exhibit symptoms of discoloration in the leaves and shoots, and I have known a dusting of lime and soot over the affected parts prevent this spreading.—A. W. WARD.

#### RICHARDIAS.

THESE plants are now in every garden, everybody knows how to grow them, and, as a matter of course, nobody wants to learn anything about them. I am very doubtful indeed if everybody who grows Richardias is acquainted with their capabilities, or has succeeded in securing to their plants the treatment which best suits them. It is one of the characteristics of present-day gardening that certain flowers are expected at any given day throughout the year, and, with us at least, Richardias

have got into that section of all-the-year-round plants. They require a certain treatment to ensure such a supply, but it is a treatment which exactly suits them, and therefore worth making a note of. It may also be said that it is a treatment which pays, as a grower (perhaps the largest in the north) who follows it not only places a larger quantity of spathes in the market at special seasons than any other, but keeps up a constant supply from the same set of plants.

The present time is most suitable for beginning the treatment of which I write. It is at least a dozen years since I first wrote of it, and with slight though necessary modifications it is the same now as then. Our plan, then, is first to keep the plants under glass long enough to save the foliage from damage. They cannot be put out of doors with any degree of safety here before the last week in May; if windy weather prevails, even later. In the ordinary acceptation of the word, *Richardias* will not bear "hardening off." I do not suppose any plant likes it, but this one will not put up with it. The foliage under the process becomes flaccid, brown, withered, and decays. The way *Richardias* like to be "hardened off" is to wait until the weather is warm, keep the plants on the dry side for a day or two, and well aired, and on a fine morning remove to a warm sheltered shady corner where they can stand for a week, and the hardening process will be completed alike to the gratification of the plant and its owner. The summer treatment is most simple. Our plants are flowered mostly in 10 and 11-inch pots, and at this time they are turned out of their pots, each plant divided so as to have one or two growths, saving in the process all the roots possible, and planting the divided pieces at once. If the ground is moist and the weather dull no water is given; if dry, a good soaking is allowed each piece, a strong stake put to the plant and the leaves tied thereto, and that, with the exception of hoeing, comprises the summer treatment. Spathes are produced before the plants have been long in their new quarters, and meanwhile a supply is kept up by a few pot plants which are not needed for stock. Now I think it is a mistake to supply the plants with either much manure or much water. The man of my acquaintance who produces the finest foliage, the largest plants, and the smallest quantity of bloom is the one who goes in for manure trenches and floodings of water.

About the middle of September we lift. The roots are crammed into the pots, and unfilled spaces filled with strong loam. Until the middle of October the plants remain out of doors; at that time they are housed, and are kept in a temperature of about 55°, growing and flowering throughout the winter. Any that are wanted to open quickly are placed for a week, more or less, in a stove temperature. Fortnightly applications of manure are given, and the plants are never allowed to go dry. Each spathe as it opens is cut, and if not wanted is kept in a cool dry room. With the cut end resting on wet moss they keep perfectly good for three weeks, and will stand a week or ten days in vases after that. We employ the spathes constantly for church vases, occasionally for room vases as a change from other flowers. They look best in large glasses among a setting of their own foliage, half a dozen or more spathes, according to the size of the glass, making a very effective vase. For dinner table decoration it may not be known that *Richardia* spathes give a very massive effect if used with judgment. In all these cases medium-sized spathes are better than large ones; indeed, we often use opening spathes for some purposes. Plants are also valued for room decoration. For this purpose we have had very neat little plants from seed, and flowered in 6-inch pots.—B.

### WATERING INSIDE VINE BORDERS.

WHAT I may relate on this subject, whether in opposition or corroborative of others' experience, will be advanced without any reference to what has recently been written, my sole aim is to be instructive to those who may need information. I have long held the opinion that the generation of gardeners who carried the sway when many of us were in our infancy were too fond of hard-and-fast lines, were too stereotyped in their notions and practices in fact. The temperatures must be kept almost to one figure, the composts must consist of certain quantities of certain materials, water was given at certain periods and in exact quantities, and yet in spite of all this exactitude I think I may safely say their productions would scarcely equal what are now grown by less precise and less particular gardeners of the present day. Times have changed materially even in my short career, and there are but few of us who can imitate the expensive practices of our forefathers. Fewer men are kept and more work has to be done, hence the revolution in our proceedings.

My practice with inside fruit borders is much the same as that in the case of plants rooting in pots. When they want

water they as a rule receive it, and this no matter whether before, during, or after the stoning process. When the borders are partially exhausted of fertility they receive liquid manure, it may be before the Vines or trees are started, or perhaps much later on, not a little depending upon the availability of the manure supply. It may be asked, How are we to know when a border needs water? I answer, Easily enough. It is true we cannot rattle the pot with our knuckles or with our feet if we are too stout or too indolent to stoop, but we can examine the soil with a pointed stake and to a good depth without injuring many roots. In every case, whether with pot plants or borders, it is a common practice to let them get too dry before watering, and then double the quantity of water that would have sufficed a few days previously would not do the work nearly so well. A little and often is much preferable and more efficacious than extra large quantities given occasionally, and which when reduced to figures is enough to frighten a beginner. Probably the average-sized inside Vine border would be about 24 feet by 12 feet, and if this was not allowed to get very dry 180 gallons of water would be ample at a time. This may seem a small quantity to some, but it is as much as is oftentimes available, and more than this, or say enough, for much to run through the border, would only be a waste of water, besides a certain loss of fertility carried away from the border.

Visitors here of late have been very curious to know what I was doing with several large bottles suspended under some early Vines. Some have expressed the opinion, after my explanation, that the idea is ingenious, while others, so I have since heard, seem to think it is a pity I have not something better to amuse myself with. I do not now propose to state my motives for rooting the Vines in bottles filled with various materials, but principally water, though I must admit I am disappointed with the results. At the same time, if I failed in one respect I have yet gained a few "wrinkles." What surprises me most is the amount of water absorbed from the bottles during a bright day. Although the bottles are not half filled with the roots, owing to the fact of their being twice killed, yet as much as a quart of water has been taken up from one by the Vines in the course of twenty-four hours. This was during an exceptionally clear night and day, when the evaporation from the foliage was most to be expected. During a fairly clear day about a pint is the quantity wasted, while on dull days very little is taken up, and scarcely any during the night. We may reasonably assume that much the same process is going on with the roots in the border, and therefore that waterings should not be given at stated intervals, but should be regulated according to the weather experienced and the state of the border, some borders being more absorbent and consequently do not become dry so quickly as others.

Although Vine roots form and thrive surprisingly well in water, it may come as a revelation that anything in the shape of manure kills them. This I was not prepared for, as I had hoped for very different things. Bones, charcoal, and oystershells may be added in any quantity, but quite a small pinch of sulphate of ammonia and kainit killed them in a short time. Lime also in small quantities did not suit them, and, what is more surprising, by no means strong farmyard liquid manure added to some clear water already in the bottle, although it did not actually kill the roots it could be seen that the points were all damaged and very little water afterwards left the bottle. It may be the roots formed in a border are not nearly so delicate as those in water, but whether this is so or not I am still of opinion that they may be very easily injured by an overdose of liquid manure. Doubtless there is much less danger in applying liquid manure to borders than to pot plants even, as it gets filtered, much remaining on the surface, and which is not always so well filled with roots as it might well be. Much also runs through the border into the drainpipes, this being especially the case when such heavy waterings that are thought necessary by some are given. I have seen Vines apparently at a standstill for a week after receiving liquid manure—it happened this season, in fact—and as this is about the time it takes for fresh roots to be formed in my bottles, it seems feasible enough that we had injured the roots with too much ammonia and potash. The lesson to be learnt from this is, that we should apply liquid manure also in small quantities and often, or we shall perhaps do more harm than good with it. What has our friend "Thinker" to say to the foregoing?—W. IGGULDEN.

### RUSHING INTO PRINT.

It is perhaps scarcely worth while taking up your space and my time to reply to "Head Gardener's" letter at page 419, but as it may please him to have his communication noticed by someone, you will permit me to state that I fail to identify myself with the incidents he refers

to, inasmuch as all contributions of mine to the gardening papers respecting my own productions or those of others have been strictly accurate and free from exaggeration. Neither have I been reproved by any head gardener I served under for any single line I have written. Your correspondent is evidently chagrined at some reporting and perhaps jealous of the approval of any work except his own. The circumstances, we are told, occurred many years ago, yet "Head Gardener" has not opened the sluices of his displeasure until now. It is more than twenty years since I was foreman in a lord's garden, and I fear that anything I wrote then, good or bad, would not be calculated to make such an impression as to be remembered for such a length of time. Gardeners at the age of twenty-two or twenty-three rarely figure as "graphic" and impressive writers in the Press, and I should only be too delighted to be one of the few "W. P. R.'s" of "Head Gardener's" stamp, but must be content to remain—YOUR W. P. R.

## CHRYSANTHEMUMS AND THEIR CULTURE.

(Continued from page 375.)

### SUMMER TREATMENT.

THE most important point in the summer treatment of Chrysanthemums is regularity in attending to their various wants, strict and prompt attention to the smallest matters at the proper time being necessary to ultimate success. When the plants are finally potted and placed in their summer quarters, great care should be exercised in supplying them with water. A good soaking having been given to them after potting, no more water will be required for several days, except the weather be hot and dry. Applying water to the roots when not necessary is a mistake, as this tends to make the soil sodden; therefore wait until the soil is nearly dry before giving more at this stage. A gentle syringing after a hot dry day is of great advantage to the plants. The roots run more freely into the new soil when it is moderately moist than when heavily charged with moisture. As the roots progress and the sun gains power the plants require water twice each day, and a few of them possibly three times. The soil in each pot should be carefully examined before water is given; rapping the pots with the knuckles is the best guide, and if the same person attends to them always he soon becomes accustomed to the sound of the pots, and at once knows when to give water with benefit. It is wise in very hot weather to examine the plants three times each day, say early in the morning, again about midday, and once more in the evening. Where rain water can be had it should be used in preference to any other; but where it comes direct from wells or water companies' pipes in a cold state, as is often the case near towns, means should be taken to expose it to the sun and air some time previous to using. Washing soda, used at the rate of  $\frac{1}{4}$  lb. to 36 gallons of water, previously dissolving the soda in hot water, softens it if allowed to stand twenty-four hours, and also acts as a stimulant to the plants. The notes on watering apply to the use of clear water only. The application of stimulants will be dealt with in a special article. Syringing the plants is a great promoter of healthy growth, and a preventive of insects. Syringing is best done in the afternoon or evening of a hot day. When the plants are numerous and placed in rows the garden engine is the best instrument to use, and the water should be directed to the foliage with some force by going between two rows of plants and returning in the opposite direction; the plants then receive a thorough washing which is far better than a light sprinkling with the hand syringe. In cold sunless weather the plants should not be syringed or mildew may be encouraged, and it ought as far as possible to be averted. Incessant attention should be paid to tying the shoots to their supports as fast as they grow; neglect in this may cause much disappointment at a later period, the points of the shoots being so succulent are very liable to be broken by wind, heavy rains, and other causes, thus the loss of these branches reduces the chances of success to a minimum. When the branches which are intended to produce the flowers are selected remove all the other side growths promptly as they appear. Allowing superfluous branches to remain weakens those that are intended to produce flowers, therefore pay strict attention to the removal of excessive growths; it is much easier to take them off when young than when they get hard.

### INSECTS AND DISEASES—REMEDIES.

Chrysanthemums are not troubled with many forms of disease or insect pests, like some other kinds of plants, owing probably to their hardiness; still they are liable to be attacked by a few enemies, but if these are attacked in turn as soon as detected, and treated as I will endeavour to explain, they will not cause serious trouble by their presence. Green fly is one of the most persistent and troublesome of insects; it attacks the points of the shoots in all stages of their growth, more particularly when the plants are young, often before the cuttings are taken from the old plants, and if a remedy is not applied the young leaves and points of the shoots

are soon crippled. The best way to clean the cuttings from green fly before inserting them is to rub with the thumb and finger the parts affected in water. This does no harm to the cutting, and the enemy is washed away. Gishurst compound used according to the instructions printed on the boxes is sometimes used, but is liable to injure the tender leaves. Fumigating the house with tobacco paper is of course quite certain to kill the fly, but it is not always worth while to fumigate a house, as perhaps a few of the plants only are infested. Tobacco powder sprinkled on the points of the shoots is the best way to remove green fly when the plants are established in pots, a good syringing afterwards cleanses them from both fly and powder. Black fly is sometimes troublesome to the young leaves on the points of the branches; it may be destroyed by dipping the parts affected in a weak solution of tobacco water, using a saucer to contain the liquid. Care should be exercised in bending the young branches, as they are very liable to snap off if bent too quickly in covering the leaves with the liquid. A leaf-mining maggot, similar to that attacking Celery, is often very troublesome in the spring and during June, when the plants are from 3 feet to 4 feet high. The maggot can easily be seen under the skin of the leaves, where it secretes itself and quickly destroys the tissues, giving a serious check to the plant. Hand-picking persistently followed is the only efficacious remedy I know; either squeeze the part of the leaf where the maggot is seen, or pick them out with the point of a knife; neglect this and the plants may be spoiled. Another enemy, like the Rose maggot, often causes much anxiety and loss by destroying the points of the shoots in August and September, when the flower buds are forming. Incessantly watching for and destroying the grubs by hand is the only means to remove these depredators. Earwigs are also troublesome when the flower buds are formed. Their favourite hiding place is among the young unfolded leaves. The tender flower buds are, however, their favourite morsels, and these they spoil by eating away the centre; but they cause far more trouble when the blooms are expanding, as they eat the florets, thus rendering the flowers shapeless. Search for them after dark with the aid of a lantern, and destroy them then, as they are not easily seen during the daytime.

Mildew is the worst pest the Chrysanthemum grower has to contend with. It makes its appearance in small spots on the leaves at any stage of growth, more particularly in damp sunless weather towards the end of summer. Brown sulphur, owing to its colour, being the least objectionable sprinkled on the affected leaves is the best remedy. This parasite attacks the under parts of the leaves, to which it is almost impossible to apply sulphur in a dry state; recourse must then be had to a liquid application. The plants are often badly infested with mildew when they are ready for housing. They should not be removed into their final position until the pest is eradicated. This is best done by laying the plants on their sides and syringing them, thoroughly wetting every part with the following mixture:—Place 2 lbs. of sulphur and 2 lbs. lime, which has not been slaked, in ten quarts of water, and boil for twenty minutes. For syringing on the plants use two wineglassfuls of the mixture to four gallons of clean cold water. A syringe with the jet affixed, causing a single stream, is the best method of applying the liquid; by placing the forefinger over the orifice the liquid can be directed upwards and spread over the plant where required. If a slight discoloration of the leaves follows from the sediment of the mixture this will not be injurious, but it can be removed if desired by a vigorous washing with clean water.

The only disease which affects Chrysanthemums to my knowledge is the following:—In the months of August and September after three or four successive rainy days the leaves from the soil to about three parts of the way up the plants turn black. I do not know any name for this form of disease, but I have noted that where soil of a retentive character is used the disease is the strongest, thus suggesting that sluggish or defective root-action may be a cause of the evil; therefore the only preventive I can suggest is to prepare the soil for the final potting in the manner previously described, thus reducing the chances of the disease appearing to a minimum. If no other course is left to the cultivator but to use a retentive soil it should not be rammed very firmly in potting, or the water will not pass away so quickly as is desirable. I have seen plants denuded of three parts of their foliage in a few days by this disease, and receiving a serious check in consequence.

### SPORTS AND FIXING THEM.

Chrysanthemums have a tendency to sport into various colours. Many of these when "fixed" are improvements upon older kinds. Some persons speak disparagingly of this method of obtaining new varieties, but I fail to see why they are not as good as those produced from seed. Many new forms of the Incurved section are procured in this manner, notably Lord Leicester. This I regard as one of the best varieties in existence, if not quite the best of the Incurved family, as it will produce more first-class blooms on a

given number of plants than any other which I am acquainted with. It originated as a sport from Golden Empress in the hands of an ex-policeman in Somersetshire, who was fortunate in fixing the sport and distributing it amongst horticulturists. The present general system of growing Chrysanthemums for the production of large blooms is not favourable for increasing the number of new varieties by sports, as the side shoots are taken off the plants as they grow, and it is from these side shoots, when they are allowed to develop into flowers that the largest number of sports appear. The best method of fixing sports and obtaining a stock of plants of the sported variety is the following:—If one branch only produces the new bloom cut away all other branches, and remove the dead bloom from the "sport," but not the leaves; turn the plant out of the pot and lay it on its side in a propagating house or frame which has bottom heat, and cover the roots and branches with cocoa-nut fibre, burying the buds in the axil, but not the leaves. This induces shoots to break at each joint, and when these are long enough take them off as a cutting with a sharp knife, but do not cut too low, as that might prevent other young growths springing from the base. Insert the cuttings singly in small pots, using sandy soil, place in a propagating case with bottom heat, and attend to carefully with water and shade. Plants which have been thus established should produce flowers of the new variety. Some growers cut the stem into lengths, but these do not strike freely, and a very small number of plants can be raised in this manner as compared to the system of inducing new growth to start from the buds. It is advisable to strike all cuttings growing from the base of the plant carefully, marking them, as some may perfect flowers of the sported variety.—E. MOLYNEUX.

### GARDENERS AND PREMIUMS.

It requires two to make a bargain, and it is evident that there are plenty of men willing to pay a premium of £5 or £10 for one or two years. A gardener, however energetic and pushing he may be, cannot do the whole work required in a large establishment, and therefore must have assistance. Young men are eager to enter large establishments, especially if they have a name, for they naturally conclude that gardening is "better done" in such places than in those of a smaller size. They offer premiums, or their friends do, and are in consequence taken on when there is a vacancy in preference to men who will not pay. That this is a fact I know by my own experience. I have been offered premiums many times from young men, gardeners, and from the friends of young men. This spring no less than three such offers have been made me without being sought.

When I took charge of these gardens over eight years ago four men were paying premiums of £10 each for two years, two having paid nearly the full amount, one about three parts, and the other half. Whether these men would have been willing to pay me the remainder I do not know, but, knowing the circumstances of their case I announced that premiums would not be taken from them and that they could all remain, provided they conducted themselves properly and did their work. Since those men left I could have filled every vacant place with premium men had I desired to do so.

There is another side to this question, and that is, that there are gardeners who will not engage men unless they are prepared to pay the premium they require for a certain length of time. At the expiration of that time they are sent to some nursery to take their chance for a place in another garden, or if they are not willing to enter a nursery they are soon treated coolly. This is not mere fancy, but a fact that can be proved. Frequently the premium system in gardens has commenced with taking one or two improvers who may have perhaps served a term only as boys in some second-rate garden, and they or their friends are anxious to give them a good start, hence a premium is willingly paid to establish them in a garden of some pretension. I see but little harm in this if it went no further; but some gardeners, like other individuals outside our profession, do not possess the virtue of unselfishness, and therefore are only satisfied when the whole of the young men under them are paying premiums. I have known this system extend to the foreman, so that room for a fresh one could be made by elevating the oldest hand to that position until his time for paying expired.

Such a system cannot be too strongly condemned, for it not only tells materially against the young men, but also the garden in which they are employed. It is worse for the latter, in fact both, when the foreman is one of themselves instead of being a thoroughly competent person. The person who benefits by this practice—which is not uncommon—is the one who receives the money, and this is more apparent than real, for his reputation, as well as that of the garden, soon suffers, and in the end he is the loser. Premium men are in most cases less experienced than could be obtained for the wages they receive. The consequence is that they are a source of annoyance to the foreman and render his duties threefold more difficult, for he in a large measure is responsible to the chief for all their actions. The majority of them have to be shown or told every little thing, or blunders perhaps of a serious nature occur, which often is the case. Frequently when they are told and shown, mistakes are made, not wilfully, but through inexperience. In a large garden where the whole of the men are incompetent to do the work required of them, the foreman, however good he may be, has a very trying and by no means a desirable

post. On him falls in no small degree the task of teaching, and the daily difficulties that arise through lack of experienced men to assist him in satisfactorily carrying out the many and varied duties entrusted to him. Under such circumstances the reward for labour done is paid to the wrong person, for instead of the chief receiving the premiums I think the foreman is more entitled to them. Young men that pay premiums generally receive as much wages per week as experienced journeymen can be obtained for. The latter will not pay premiums, for they are in demand in plenty of gardens where the gardener, rather than enrich himself by a few pounds annually, is anxious that his own reputation should not suffer as well as that of the garden. If an employer allows his gardener to take premiums to make up his wages, and men are willing to pay them, I do not see that anybody else has anything to do with the matter; but employers had much better pay their gardeners an extra £10 or more a year, as the case may be, for in return they would be repaid more than twofold.

It may be argued by the advocates of premiums that men appreciate more highly the knowledge gained if they pay for it. Perhaps they do, I will admit this point for the sake of argument, but it must be remembered that gardening is not learned in two years. If men appreciate that for which they pay, and pay only for one or two years' service in some good garden, they have not much to appreciate. There is another side; perhaps they lose more than they learn. When a man knows that he is secure for a certain period of time he invariably makes but little if any progress, and at the end of the term is no better than at the beginning. There is a tendency in all of us to grow indifferent, and I know nothing more certain to produce it with many men than security for a time. It causes carelessness and after negligence, from which they are only roused by some individual who will have the work done properly, quickly, and intelligently. They realise then that it is necessary for them to push, or they will be dismissed, and this is the turning point in the lives of many, and in others the end of their gardening career. Do not let me be misunderstood, for all men who pay premiums are not careless and negligent, for some are sharp, persevering, intelligent, pushing young men. I have had some of the indifferent and slothful as well as some of the latter from premium establishments. Security for two years through paying a premium has this tendency, for it is certain that gardeners will not discharge them unless they become intolerable until the amount agreed upon has been paid.

It has been said there would be an insufficiency of young men in the gardening profession if it were not for these apprentice establishments. Such is not the case, for there is work in nearly all gardens of any size for one or more boys, and there is no difficulty in obtaining them, and most of them now are better educated than the present race of gardeners were when they were boys. It is uncharitable to keep these boys back because they are not in a position to pay premiums. Many of them in consequence are destined to be labourers, for there is no other prospect for them without someone kindly takes them by the hand and pushes them forward to give them a start. I thoroughly believe there would be less second-rate young men wanting places to-day if the premium system was abolished.

The question of dress has been raised, but many a young man might be termed "dressy" when he enters a fresh garden, for there are plenty of young men who turn out their old things and enter upon their new duties in a highly respectable manner, perhaps it may be with a new suit of clothes. I have had several who have done so, and further, I have in the past done the same myself. It invariably follows that a man who is clean and neat in his dress is equally so in his work. I like to see young men respectfully dressed, and should be one of the last to interfere with a man on this point. Gardeners are not justified in dictating to a man what they are to wear and what they are not to wear. Young as well as head gardeners have a perfect right to liberty of opinion on this subject, and as long as the former keep themselves sufficiently respectable, according to the work they have to do, that is all we have any right to expect. If a young man were engaged for table and house decoration, I should certainly expect him to be better dressed than the man engaged to dig and work in the kitchen garden. I am no advocate for rings, or the wearing of jewellery of any description, and would not wear a ring if I had one given me. Other people, however, have a perfect right to please themselves, and if a man desires to wear a ring, and he does the work required, I fail to see what right a gardener has to complain. The employment of gloves when stoking need not be discussed at any length. I have provided strong leather gloves for my men ever since I have had the charge of a garden, and had them found for me previous to that, and highly appreciated the thoughtfulness of the gardeners who did so. It is impossible for a man to keep his hands clean without their aid. Stoking and watering for a week means two or three weeks' labour before the hands are thoroughly clean again. This is not all, for many men's hands crack badly through being wet and then half roasted in stoking large boilers, watering, and other inside work, and then stoking is very trying to the hands, however soft the skin may be to commence with. Gloves are not very expensive, as they last a good length of time if re-stretched by a sadler previous to being used.—A LOOKER-ON.

"OUTSIDE FOREMAN" appears to have introduced a very much more pleasant and practical tone into this subject. If the majority of young men could be treated and worthily make progress as sketched out, perhaps less might be said against this rather doubtful practice. Your correspondent says, first of all, "I cannot see why a premium should not be paid by an apprentice in our profession just the same as by an apprentice in any other trade and profession?" I am inclined to think, if this

formed an important argument, the right of taking premiums would soon disappear. In the first place, it is very questionable if the term apprentice applies to 5 per cent. of gardeners; there is seldom any legal tie. And, again, in most cases it is not the youths that are first entering gardens who pay premiums, but young men who have already served some years, and for improvement seek a beneficial change, and when he will certainly have a full share in all duties. This being so, may I ask where "An Outside Foreman" sees the resemblance between gardening and other trades? Singularly enough establishments which deal most in premiums are often in the habit of paying the lowest wages. I could enumerate a few rather glaring shortcomings of premium-payers, but have no desire to slight young men.

In my opinion, however, receiving premiums is not a good practice. If a young man wishes to learn nothing can prevent his doing so; and, on the other hand, if he is slothful he will never be a competent gardener, and the sooner he retires to some other calling the better for all.—**LATHYRUS.**

### STRAWBERRIES.

As it is proposed to have a Strawberry election to prove which are the most useful sorts to grow, I will give my evidence. I have grown upwards of a hundred varieties, one-half of these being seedlings. Owing to ill health I have lost sight of half a dozen extra good seedlings, and in this climate I cannot grow successfully earlier sorts than Garibaldi, nor later ones than Dr. Hogg or Elton Pine. I have a seedling of the British Queen type, coloured to the very point, and very hardy. I have tried Dr. Roden's Early Prolific and others, but it appears we are too far north for the successful cultivation of his seedlings. The soil is light, resting upon a bed of gravel at a depth of from 1 to 2 feet. Roses will not thrive in it, but Strawberries do well, only they must not be kept long in the same place. As annuals they do extra well. Care must be taken, too, that a new plantation be not formed earlier than six years after a plot has been dug.

Garibaldi, which, with me, is distinct from, and superior to, Viscomtesse Hericart de Thury, I place first as a prolific, strongly constituted, free grower, good sized, and of a Keens' Seedling flavoured fruit.

Almost as early, but having much larger fruit, and lasting longer, is Dr. Livingstone. This is a seedling from Admiral Dundas, not unlike President, but it is rather firmer, has a brighter appearance when growing, but does not colour so well on the side farthest from the sun, is fine flavoured, and produces more fruit than any other variety I have grown. For marketing purposes I am told it stands first in Glasgow. The Editor of this Journal reported favourably of this Strawberry some fifteen or more years since. So did Mr. Barron. There is no Strawberry I have seen that will produce a crop beneath trees as this one does. It appears to be at home in all soils and situations. If I were confined to one sort it would be this one. If two, Garibaldi and Dr. Livingstone. For a firm, fine-formed, and good flavoured Strawberry, Sir Joseph Paxton, but with me it is uncertain after the first year, and many plants come blind. Were this not so it would be a great favourite.

As Dr. Livingstone lasts so long. I go from it to the later sorts. Dr. Hogg is a handsome variety, and should be in every collection. Duke of Edinburgh does not grow well with me, and as flavour is the first thing in a Strawberry, I discard it and James Veitch as being defective.

Cockscomb at one time grew large berries and was well flavoured and very prolific, but after a while refused to grow. Although coarse-looking, it is an interesting fruit, and I would not exclude it from a collection.

Frogmore Late Pine did not do well here, being too tender, but otherwise a handsome well-flavoured fruit. Elton Pine, although soft and a little acid for dessert, is good for preserving, is very prolific; with large, well-formed fruit. It does well here.

Although these are my selection, I would advise for their great prolificness and earliness some Black Princes. If grown right it is not at all a small berry, and has a peculiar piquant flavour strictly its own. Then where Keens' Seedling can be had true, it, in addition to its fine flavour, seems to be an everlasting Strawberry. Near me there is a bed of them still doing good service that has not been disturbed for thirty-five years, and yet it does well, but it is the true sort.—**W. THOMSON, Auchinraith, N.B.**

### REVIEW OF BOOK.

*Orchids: Their Structure, History, and Culture (Illustrated).* Second Edition. By LEWIS CASTLE. 171, Fleet Street.

THE still-increasing demand for Orchids is exemplified in the numerous recent publications devoted to their culture. By one post I received the excellent treatise alluded to above, and the "Reichenbachia," by Mr. Fred. Sander. The last, a magnificent serial monthly publication, containing four coloured plates, which no doubt every Orchid grower will subscribe for. In Mr. Castle's book no less than forty-one publications on Orchids are enumerated, but as the author justly observes, many of them are far too expensive for those who have slender purses. We cannot be all so careless of money as the gentleman described by a celebrated American author who "handed his servant a bill without looking at it, and pocketed the change without counting it." Nevertheless, I make bold to say that hundreds of young gardeners, and old ones too, spend more money on tobacco, and waste more time and money in public houses, than would be required to purchase the "Reichenbachia," and many other expensive and useful books. I make no special charge against gardeners that might not

be made against any other class. The only remark I make about Mr. Castle's book in respect of its price is that it is too cheap. It costs but a shilling, and half of that sum must have been spent on the binding. The book itself contains 104 closely printed pages brimful of most useful and suggestive information, gleaned, as the author states, from "many years' observation." The book opens with a chapter on "floral fashion," and some interesting information is given there and elsewhere about the prices of Orchids. Rare and beautiful Orchids will always command a high price, but, as the author remarks, a nice little collection may be purchased for £5; and, to confirm this, I may say a gentleman told me last week he paid £5 for his first lot of Orchids, forty plants, and sold half of one of them subsequently for 20 guineas. Rare varieties of Orchids, worth 150 guineas, have been purchased in the usual way for half-a-crown; but the large proportion of Orchid fanciers comprising an ever-increasing number of busy city men, grow Orchids for nothing but love of their plants; they are fascinated by the quaint forms, endless variety, and sweet perfume of the lovely flowers.

A chapter is devoted to a description of Orchid flowers, which will be of the utmost value to young gardeners and amateurs; the descriptive remarks are illustrated by woodcuts of the pollen masses, stigma, column, labellum, nectary, ovary, &c. A study of this chapter and that on "Fertilisation" would enable anyone to commence hybridisation without going any further for information. The cultural remarks are very trustworthy, and may be followed by the most nervous cultivator without fear. The use of manures is alluded to, but to be applied with caution, "or much injury will result, and beginners had better abstain from dangerous experiments until they gain more knowledge of Orchid culture." Mr. Borwick's Orchids at Higham Hill, Walthamstow, are alluded to as being much improved by the use of Jensen's fish manure, and used with caution excellent results have followed. In all cases when this or any other manure is used it is best to proceed by taking a set of say twelve plants all alike, use the manure upon six of them and none at all upon the other six, grow them together and watch the result for twelve months. Another hint may be useful. A gentleman read somewhere that he was to use so much guano sprinkled on the surface of the soil in a 15-inch pot. This seemed plain enough, but he measured round a 5-inch pot, gave his plant an over-dose and killed it. Having seen Mr. Borwick's plants, I can say that his examples of *Lycaste Skinneri* grown in pure leaf mould and "fished," as he calls it, have grown with amazing vigour, the pseudo-bulbs formed last year being in many cases quite three times as large as those formed the year previously. Other specimens, such as *Maxillaria grandiflora*, were equally remarkable. Mr. Castle's chapter on culture and the use of manures should be read by every Orchid grower. This being the only cheap and at the same time reliable work on Orchid culture, it will doubtless soon be out of print. For my own part I am puzzled beyond measure to understand how such cheap books can be sold at a profit to the publishers. I fancy some of them must be in the case of a caterer of shilling dinners for a great exhibition, who at last found himself in the bankruptcy court, and it came out in evidence that the average cost of the dinners was one shilling and three halfpence, and he had trusted that the large number of dinners required would pay in the end.

I ought to add that the frontispiece is a life-like portrait of the President of the Royal Horticultural Society, Sir Trevor Lawrence, Bart, M.P., and the conclusion is an Orchidist's Directory and a capital index.—**JAS. DOUGLAS, Great Gearies, Ilford.**

### GLOXINIAS FOR AUTUMN FLOWERING.

THE system recommended by Mr. Udale, page 394, of planting out Gloxinias in frames so as to have a good supply of blooms with a small amount of labour and expense, is well worth a trial by all who grow these plants in large numbers for cutting. Gloxinias can also be had in flower in abundance during the autumn months if treated in the following manner. About the middle of June place some Gloxinia leaves in small pots, using a light compost, such as leaf mould and a good sprinkling of sand, plunge in a steady bottom heat, keep a moist atmosphere in the house or pit, but not too moist, or the leaves will damp instead of making roots freely. When they have rooted, transfer them into 4-inch pots. Use for this potting two parts good fibry loam, one of leaf mould, and one of sand, also adding some well-decayed cow manure if it is to be obtained, not made fine, but in lumps about the size of a walnut. After potting, place them again in a brisk bottom heat, keeping plenty of moisture around them. Be careful in watering till the roots have taken possession of the new soil, then, every third watering or so, give weak liquid manure, and, if so treated, good results may be anticipated, and would serve to keep up a succession of bloom. Some flowers produced by plants grown in the manner stated were in the hand bouquet which was awarded the first prize at one of the leading Chrysanthemum exhibitions held last November.—**G. GARNER, Amberwood, Hants.**

### VIOLET FLORIBUNDA

IN perusing the interesting article on Violets in your last week's issue, I was rather surprised to find floribunda classed amongst the spring-blooming varieties. This variety I raised from seed (The Giant) a few years ago, and if there be a perpetual-blooming Violet I consider floribunda is the one. It is always in flower by August, and you may often find a few flowers on it even earlier than that. It is certainly the freest bloomer I know and as early as any, and although not quite so

large as *Victoria Regina*, it will bear a dozen blooms when the latter would bear one, and as sweet as any. I fancy your correspondent has not grown the true one, as he terms it a small flower.—G. W. BOOTHBY, *Louth*.

### PLASHING HEDGES.

ARTICLES were published in our columns a few weeks ago on the management of hedges, and a "Bailiff and Gardener" advocated, on page 333, the method of plashing which is successfully practised in some districts. We have since had inquiries for details of the method, and have pleasure in publishing the following letter with sketches supplied by a gentleman in Lincolnshire. Mr. Beulah, Manby House, Raven-thorpe, writes:—

"My daughter has sketched a portion of hedge newly plashed, fig. 81; it is exactly like the portion she copied. As a guide to readers she has also sketched a piece of two years' growth since plashing from nature and

Fig. 81.—Hedge Plashing.

trimmed last autumn for the first time (fig. 82). Our usual practice here with hedges, old and new, is to plash or lay them every few years; even after hedges are closely trimmed for several years it is a good practice to let them grow up (wild, as it were) for a few more and then plash them. New quickset hedges should also be plashed after about eight years' wild growth. When done by a skilful workman they never fail to make good fences. Large old fences sometimes require a rope to lower the tree-like branches down, and when these are well done and planted in and out they make a fence sufficient to prevent any domestic animal, or even a lion, from passing through. We let them grow two years before siding up which we do in the form of an inverted V, or wedge shape.

"The cost varies from 1s. 6d. per chain of 22 yards for young hedges to 4s. for old bullock fences. We have down here about a mile, 80 chains yearly for the past four years, and some of the earlier are now very good sheep fences. When the land is grazed by beasts a dead fence called a "Beard" is placed 3 to 4 feet from the side of the hedge when there is no

Fig. 82.—Hedge Two Years Plashed.

ditch. As to the latter, we have them always kept open whether there is water or not to be taken off the land, and a good workman when he makes a good bank, fresh soiling the bottom of the hedge which has been plashed, makes, to my mind, one of the best-looking jobs about a farm."

The growths are often too numerous for laying down, and several are chopped out close to the ground, the young growths which start from the stumps contributing to the closeness of the fence at the base. When these plashed hedges are properly trimmed they are not only strong but as ornamental as could be produced by any other system of management. The laid branches or "ribs" of the hedge are soon entirely hidden by the growths. As was stated by a "Bailiff and Gardener," binders are often

run along the top of the stakes, which increase the rigidity at the first and impart a neat appearance.

### THOUGHTS ON CURRENT TOPICS.

IT is very easy to think too fast, or at least to record impressions too hastily. For once at least I appear to have exercised a little caution in waiting to hear the other side of the question in respect to the alleged extortion of money from a young man under circumstances that have been described. It would also appear that while it is easy to "rush into print" hastily there is the possibility of waiting too long for evidence, and thus find the case closed. I am debarred, then, from saying what I think on the particular case that has agitated the minds of correspondents, but not from referring to the subject of "premiums generally." I do not, however, imagine that the jury has lost much through my absence from the witness box, for the moment I saw the intimation of a "strong petition" announced I made up my mind to say very little on the subject in dispute, feeling it would be more seemly to wait the issue of events than to enter largely into the discussion of a question under those circumstances.

ON the general subject, then, of the payment of premiums by young gardeners one or two thoughts naturally arise. There is clearly the possibility of a young man paying £5, or any other sum, "down," for the privilege of working in a certain garden, then after a few weeks proving his incompetency for the duties pertaining to his charge. 1, Would a gardener be justified in keeping such a man? 2, If he did keep him, would he not be spending his employer's money in the form of wages for services not satisfactorily rendered? 3, If, as a faithful steward to his master, he discharged the man, would he be justified in keeping the £5? 4, If a man is sent away as incompetent, on what grounds would a gardener be justified in stopping any portion of the pupil's wages for the period of his admitted incompetency? 5, Is it legal for any portion of a man's wages to be deducted at all in the absence of any covenant signed by the gardener and sanctioned by his master (whose money is diverted) and by the man who agrees to its diversion? These appear to me to be pertinent, proper, and not unimportant questions directly bearing on a subject in which three parties are directly interested, all of which have an inalienable right to equal justice.

A VERY excellent letter, as it appears to me, on the general subject of premiums was published on page 398, from "A Gardener to an Earl." He does not say whether he receives premiums or not, but if he does it is clear he feels morally compelled to personally interest himself in the training and welfare of his pupils, and feels bound to advance them in life, or in other words, to give "value for money received." That is as it should be, and in such cases there can be scarcely any objections to the practice, provided pupils are worthy and fairly earn the money that is paid by their masters; but in some cases there is reason to suppose that whatever is taught the young men is taught by their foremen, who, I think, do not, as a rule, share in the teacher's "pay."

THE system of premiums for learning gardening will die out, just as premiums for apprentices in trades are dying rapidly. I am no advocate for "snuffing out," as that is attended with injury to individuals, and gradual and natural changes are, I think, the safer and fairer for all. I see "Observer" rather contemplates a retrograde movement, and appears to be considering the advisability of the imposition of premiums on the ground that young men are not sufficiently "grateful" for the teaching they receive "gratis." I rather suspect, however, that gratitude is an inherent virtue, and I think the man who is not grateful for what is given him will not be extra grateful for what he pays for. I have learned a little of gardening through paying, a little without, and I do not feel more grateful to the men who shared in my small wages than to those who did not, while I was taught much more by the latter than by the former. If "Observer" has experienced benefit from paying, and his gratitude has been deepened towards those who have received his money, he has then grounds for his projected change. I have none, and if I have not taken a penny from a gardener, it is not because I have not had opportunities for "making" several £5 notes. However, this is just a question of feeling, and I am willing to believe that "Observer's" motives in accepting premiums, if he conclude to accept them, are just as good as my own.

AN "Outside Foreman" contributes a sensible letter on page 417. He admits having had good value for his £10, and at the same time points out some of the evils attending the premium system. Paying money does not make able men. It opens the door to appointments, as in the instance cited, giving young men of sense an opportunity of becoming good gardeners; but "fops" innumerable have bought their way into positions, and their services were dispensed with as soon as possible, and thus the country has been flooded with failures, who pass as gardeners, to the prejudice of really able and accomplished men. It is readily granted that some of the best gardeners in the kingdom originally paid for their learning; but there are others just as good who paid no premiums. The custom can only be justified on the principle indicated by "A Gardener to an Earl," if then as regards the master's or wage-payer's interests, and it will die out—in fact is dying—for I know at the least half a dozen gardens where it has lapsed, and it is not likely to be

resumed. But I have said enough, and some others can have their "say" on the subject if they like.

SOME common-sense remarks on Asparagus appear on page 415, but neither of your correspondents tells us what I think not a few readers wish to know—namely, whether cutting the small growths known as "spray" as they spring up in the beds towards the end of April or early in May weakens the plants or the reverse. Some old and successful growers chop them all off till about the middle of May, while the younger school permit them to grow. Considering the matter philosophically this would appear the right course to adopt, but is it? What do Messrs. Iggnlden, Muir, and others who may have tested the matter say? It is very certain that late cutting or clearing off every head as thick as a pencil till the end of June is injurious, and has permanently weakened many beds of Asparagus.

I READ with much pleasure Mr. Udale's excellent article (page 395) on planting out Gloxinias. I remember once seeing 50,000 planted out in frames, and I shall not soon forget the wonderful effect produced. They were seedlings raised in February, transplanted and grown in boxes till June, then planted in light yet generous soil. The corms produced by these plants were much finer in the autumn than those produced by plants from the same batch grown in pots. I have tried the plan exactly as recommended by Mr. Udale, and in no other way have I produced such a supply of handsome flowers for cutting, with such little trouble. Gardeners and others having spare frames and partially exhausted hotbeds, also some sturdy young seedling Gloxinias, might do worse than follow the advice tendered on the page quoted.

IN the matter accompanying the beautiful figure of Dr. Duke's Odonoglossum on page 403, I find a few lines worthy of being brought into greater prominence. Here is the sentence:—"A point observed at The Glen, that is also studied in other establishments, is to have the floors of Orchid houses of earth, both the paths and beneath the stages, for a more steady supply of moisture is thus afforded than from brick, tile, and stone floors." There is more "in" that small paragraph than many persons imagine, otherwise we should not see so many smooth, poreless floors, even iron grating, where it could well be dispensed with in Orchid houses, forcing houses—indeed, in plant and fruit houses generally. Gravel paths neatly kept are the reverse of unsightly, and might with great advantage be found in numbers of supply or preparing houses in gardens. They are cheaper, and in every way better than smooth fancy floors, being much more conducive to the health of the occupants of the structures and as preventives of red spider and other pests that invariably establish themselves the soonest where there is no earth moisture. Architects' ranges and conservatories are too often great insect nurseries and plant death traps, a source of never-ending trouble to gardeners and a credit to nobody. If I were having Orchid houses or forcing houses erected and could have them paved with glazed tiles for nothing I should decline the proposal, knowing the gift would be dear in the end. Dry open stages over hot-water pipes, iron gratings, and smooth dry surfaces are inimical to the health of plants, Vinos, and trees, and ought to be dispensed with as far as possible in favour of a moisture-yielding base. It is the dry air in many structures that more than anything else prevents the healthy growth of Orchids and other plants. I am glad "L. C." incorporated that useful sentence in his interesting article. Descriptions of places should always, in my opinion, contain practical hints, as they mostly may do; then are they both agreeable and instructive.

ANOTHER example of the embodiment of instruction with description is afforded on page 381, in connection with the apparently most effectively arranged and decidedly attractive winter garden there represented. It is observable, too, that the paths are of gravel, and scarcely a doubt can be entertained that if they were paved with smooth ornamental tiles and the plants arranged on stages that the effect would be less pleasing, at greater cost. Granting the trustworthiness of the young men and Mr. Sanders' good management, the health of the plants, and Rose on the roof, is in a great measure due to the earth moisture steadily rising from the beds and gravel paths. Dry air acting on the under sides of the leaves of most plants is unquestionably inimical, and I can never suppress a feeling of pity for gardeners who are in charge of high, dry, smooth, prim and polished architects' conservatories. Experienced horticultural builders can design and erect structures as ornate as is desired in which plants will thrive, and it is very deplorable to see so much money expended on buildings that do not, and cannot, satisfactorily answer the purpose for which they were erected, as designed by persons of great skill in their own line or profession, but who know little about the requirements of plants. Gardeners should be consulted in the erection of garden structures and the work carried out by horticultural builders if the requisite expenditure is to prove a satisfactory investment.

WHAT curious people there are in the world! That is what I thought when reading of someone "poking fun" at "D., Deal," for transferring his Lapagerias from pots to boxes. Some of the finest plants in the kingdom, excluding those planted in borders, are in boxes, in which, as a rule, Lapagerias grow better than in pots. A more equable temperature and root moisture can be maintained in the former. Given an abundance of drainage (charcoal), so that much water can be applied without souring the soil, a shaded rather than a sunny position, a rather firm yet springy compost of very fibrous peat mainly, and Lapagerias are bound to grow. The more water they receive, when established, provided the soil is sweet,

and the less sun in hot weather, the more luxuriant they are, and, like Orchids, they appear to grow as well in towns as in the purer air of rural districts. Mere descriptions of gardens without a suggestive hint are, to me, bald and profitless. One of your correspondents' "descriptive hints," given some years ago, and briefly repeated on page 396, enabled me to grow satisfactorily the "Flower of the Gods," *Disa grandiflora*. Gardeners and garden lovers want, and must have, something to read, but they like those narratives the best that have "something in them;" at least that is the opinion of—A THINKER.

### CULTURE OF THE HYDRANGEA.

IT is now some ten years since I first detailed in the *Journal of Horticulture* the mode of culture practised by the London market growers for producing Hydrangeas in 5-inch pots, with heads of bloom from 12 to 18 inches across, and as it differs somewhat from that detailed by "G. G., Hants," at page 408, I will describe it again, as it may benefit numerous younger readers.

In the early spring large plants of well-ripened wood are introduced into an intermediate temperature fully exposed to the light and air, so as to make the cuttings sturdy. These are taken off, not necessarily with a heel, when the cuttings are strong enough, the size selected being those which have about two pairs of large leaves and a plump terminal bud. The two undermost leaves are removed, and the cuttings inserted singly and firmly up to the second pair of leaves into thumb pots, the soil consisting of equal parts of leaf soil and loam, with a liberal sprinkling of sand. The cuttings must be well watered in and plunged in cocoa-nut fibre refuse under a close propagating frame or handlight in an intermediate house or a half-spent hotbed. If kept shaded and fairly moist they will soon form roots, when they should be stood out in the open part of the house, and be eventually removed to a cold frame before they make any top growth, the aim being to keep them dwarf and sturdy. After they are hardened and are fairly rooted, transfer them into 5 inch pots, the soil to consist of four parts turfy yellow loam, and one part each of leaf soil and well pulverised manure. Pot the plants firmly, and return them to the frame until the roots commence taking to the fresh soil, when they should be removed outside. The best position is on a bed of coal ashes fully exposed to the sun and air, which is an important point, to insure dwarf plants. Watering must be carefully attended to, as on no account must the soil be allowed to become dry. Stimulants must be avoided during the summer, as that would excite them into growth instead of forming a plump terminal bud, but a little soot water would be beneficial.

The plants must remain in the open air until frosts appear, which will cause them to lose their leaves, when they should be removed to a cold frame for the winter. Plants should be introduced into a light intermediate house early in March, and others at intervals so as to form a succession. Clear soft water must only be used until the flower buds appear, at which time stimulants must be applied so as to force the head of bloom to a large size. Dryness at the roots must be especially guarded against, as the pots would be filled with roots.

Large quantities of decorative plants may be grown in a simple manner if the work is well managed.—A. YOUNG.

A SELECTION of the best plants in the late PROFESSOR MORREN'S COLLECTION OF BROMELIADS AT LIEGE has been purchased for the Royal Gardens, Kew, and form an important addition to the already extensive collection of these interesting plants in that establishment.

— WE learn that MR. GEORGE NICHOLSON has been appointed Curator of the Royal Gardens, Kew, succeeding Mr. John Smith, who recently resigned after twenty-two years' service. Mr. G. Nicholson has assiduously performed the duties of Assistant-Curator for fourteen years, having been originally appointed clerk to the Curator in a competitive examination. Mr. W. Watson, foreman and propagator, succeeds Mr. Nicholson as Assistant-Curator, but retains charge of the indoor department, which has been under his superintendence for several years, during which time the collections have steadily improved.

— MESSRS. JAMES VEITCH & SONS are now sending out a distinct and handsome plant under the name of *IMPATIENS EPISCOPI*. It flowers with the same remarkable freedom as *I. Sultani*, but is of more compact habit, and the flowers are of a purplish-carmine colour.

— ONE of the best plant novelties of the present year is *IMPATIENS HAWKERI*, which will be shortly distributed by Mr. William Bull, Chelsea. It is like a magnified form of *I. Sultani*, but it is more robust in

habit, and the flowers exceed 2 inches in diameter. They are of a very deep carmine, almost vermilion colour, exceedingly bright, the centre being white surrounded by a ring of violet. The plant is a native of the South Sea Islands, where it was discovered by Lieutenant Hawker.

— A VERY handsome specimen of *ODONTOGLOSSUM VEXILLARIUM* is now flowering in the Orchid house at Great Gearies, Ilford. It is a *bona fide* single specimen grown from one rootstock, and bears forty-seven racemes, the total number of flowers being 289. This with several others has been grown on from small pieces in the past ten years, the plants being placed in the *Cattleya* house during winter and the cool house in summer, especial care being exercised to prevent their becoming dry at the roots.

— AS will be seen from an advertisement in another column MR. CHARLES HERRIN, who has been gardener at Chalfont Park, Gerrards Cross, for ten years, desires another situation. Mr. Herrin is well known as an exhibitor at Chrysanthemum and other shows, and has repeatedly proved his skill as a cultivator in close competitions with fruit and other productions.

— THREE new SEEDLING PHYLLOCACTUSES have recently flowered at Cromwell House, Croydon, all being most beautiful and distinct. They have been named respectively Mrs. Charles Major, Miss Dorothy Major, and Miss Mabel Major. The former is very large, of a brilliant rosy pink colour, with white filaments; the second pale rose, the inner petals rich purplish carmine, the filaments deep crimson; and the third bright scarlet outer petals, the inner petals of the same hue as that last referred to, the filaments bright rose. All are large and of fine form, and they make a desirable addition to the excellent collection of Cacti in Mr. Major's garden.

— THE INDIAN RHODODENDRONS in the same garden have been gorgeous; the plants—or rather trees—are growing in huge tubs, some under glass, others out of doors. A specimen of the lemon-scented Countess of Dalhousie has produced upwards of 1000 blooms, and another of the sweet-scented white variety, Princess Alice, bears nearly as many.

— A CORRESPONDENT, "W." writes:—"RIVINA HUMILIS forms a most attractive standard for a warm conservatory; when thus grown the long spikes with their load of scarlet berries droop gracefully over the other plants amongst which they are placed, and have a very pretty effect."

— THE first part of a magnificent new serial work on Orchids, entitled "REICHENBACHIA," is just to hand. It is by Mr. F. Sander, with "the assistance of scientific authorities," and is to be issued monthly with four coloured plates, either chromo-lithographs or hand-coloured. The present number is dedicated to the Queen, and contains plates of *Odontoglossum crispum*, *Cattleya labiata* Percivaliana, *Cypripedium Sanderianum*, and *Odontoglossum Rossi*, each 15½ inches wide by 21 inches deep, and admirably drawn and coloured. Except the *Cypripedium*, which is drawn by Mr. W. H. Fitch, they are all the productions of Mr. H. G. Moon, and the *Odontoglossum Rossi* is one of the most truthful yet artistic plates we have seen. A botanical description in Latin, accompanied by analytical drawings of the structure, is furnished by Professor Reichenbach with each plate, and some general remarks on history and culture are added in English, French, and German, which will greatly increase its value. It is published by F. Sander & Co., St. Albans.

— MR. N. DAVIS, The Chrysanthemum Nurseries, Lilford Road, Camberwell, London, S.E., sends us the following:—"It has been suggested that the time has arrived when the valued services that MR. WILLIAM HOLMES has rendered to the National Chrysanthemum Society in his capacity of Hon. Secretary, should be acknowledged by presenting him with a testimonial worthy of the Society, and a Committee has been formed to carry out this object. They feel that the success of the Society is in a great measure due to the unwearied efforts of Mr. Holmes, and to the disinterested zeal at all times evinced by him on its behalf. They therefore feel justified in inviting all members, as well as others interested directly or indirectly, in the work of the Society, to allow their names to be put down as subscribers to the fund."

— A CORRESPONDENT sends us a photograph of *PHALANOPSIS SCHILLERIANA* which he says is "the finest plant in the country—at any rate the best I have seen. It belongs to Stephenson Clarke, Esq., Croydon Lodge, Croydon. It has two strong growths with thirteen

splendid leaves, some measuring 12 to 15 inches long, and from 4½ to 5½ inches wide, all being perfect and of great substance. This year it bore four strong flower spikes, 3½ to 4½ feet long, the whole carrying 180 flowers of the finest colour and form. The plant has been growing for some years in the roof of an ordinary plant stove, and I am of opinion with Mr. Carr, the gardener, that it has greatly benefited by the evaporation of ammonia from the waterings applied to *Eucharis*, *Crotons*, *Dracenas*, &c. I have often noticed *Phalænopses* doing much better in a house with such plants than in one exclusively devoted to them."

— IT is said that the BANANA TRADE, which has proved a splendid source of income to cultivators in Jamaica and Honduras, is about to be greatly extended. Demerara intends to send us large consignments by vessels especially fitted for the carriage of fruit; and in addition to Bananas we are to have Mangoes, Pine Apples, and other tropical fruit. A ready sale may be confidently predicted if only prices are moderate.

— MR. ABBEY refers as follows to GILBERT'S VICTORIA BROCCOLI:—"Heads of this Broccoli, cut on the 26th May, were large, very firm, close, and heavy. This is the most tender and best-flavoured Broccoli I have tasted, the flavour not being at all strong, but particularly Cauliflower-like and pleasant. It must prove a great acquisition."

— LIVERPOOL INTERNATIONAL EXHIBITION.—In addition to their fine display inside the Exhibition buildings, Messrs. Webb & Sons have successfully laid down numerous extensive lawns in the grounds outside, with their prize Grass seeds, and their splendid appearance—even at this early stage of growth, and after the recent unfavourable weather—was referred to by the *Liverpool Daily Post* of May 26th in the following terms:—"The most important attractions outside are to be found on the plateau, for the damp weather, though disadvantageous in other ways, is at least bringing the lawns to that point of verdure which they should assume in order to set off to the best advantage the beautiful flowers and shrubs which have been planted in various designs by emulative gardeners, and the beautiful rockeries, which are a triumph in themselves. The plots sown by Messrs. Webb of Stourbridge are doing their part nobly towards the object named, and fairly disproving the theory that green lawns can be more quickly formed out of sods than well-conditioned grass seeds. In this instance, at all events, the very opposite is the case, the grass looking beautifully fresh and green, while many portions of the ground which had a start of them by being carefully turfed among the first operations on the plateau are looking bare and brown." At the Bath and West of England Show, Bristol, Messrs. Webb & Sons also have an extensive display of flowers, *Gloxinias* and *Begonias* being very fine.

— MR. G. BOLAS sends us from Hopton flowers of *TROLLIUS FORTUNI*, which for richness of colour he remarks far outvies its companions *T. europæus* and *T. americanus*, and has, moreover, to him a remarkable Apricot scent. The rich Apricot colour is very apparent, but the perfume appears to have departed from the flowers in transit. They are highly attractive.

— MR. BOLAS also sends flowers of *DIPLACUS GLUTINOSUS* AND *ROSEA*, and observes—"I have a plant of each in 15-inch pots, measuring 4 feet from rim of pot, and 3 feet high, giving me an abundance of flowers for cutting. They last over a week perfectly fresh in water. Two glasses now filled with these flowers, with a few of the blue *Marguerite*, the old *Agathæa cœlestis*, and sprays of the noble *Spiræa Aruncus*, form a most delicate and pleasant combination. These old *Diplacuses* would form splendid exhibition plants for spring shows, flowering from the rim of the pot. The plants in question have not been potted for over two years, are turned out of doors all summer till frost sets in, and flower, more or less the whole time if allowed."

— A MONOGRAPHIC LIST OF ANTHURIUMS, by M. E. Bergman, gardener at Ferrières, France, has just been issued in the form of a pamphlet of fourteen pages. The notes originally appeared in the *Journal* of the "Société Nationale d'Horticulture," February, 1886, and has been reprinted from that work. The species are arranged alphabetically, 125 being enumerated with many varieties. Full descriptions are given of some of the leading species, with the native country, date of introduction, authorities for the names, and other particulars. Others are dismissed in a few words, and of some the native countries only are given. It would have improved the value of the list considerably if brief descriptions had been given of all. Sixteen varieties of *Anthurium Schertzerianum* are named. A few slight errors in nomenclature are noticeable, but the list will be found a useful one by many persons.

— PRIZES FOR WILD FLOWERS.—In part 4 of the re-issue of Messrs. Cassell's "Familiar Wild Flowers," it is announced that a series of five prizes, amounting to £50, will be given for the best collections of wild flowers, consisting of specimens of those figured in the first volume (parts 1-20) of the work named. Collectors must be *bona fide* amateurs, and the specimens must be sent in not later than October 31st, 1887. Further rules and a list of the plants required are given in part 4 of the present issue of the work, which also gives coloured illustrations of the Scarlet Poppy (*Papaver Rhæas*), and the Cuckoo Pint (*Arum maculatum*) with descriptive notes.

— MESSRS. J. CARTER & Co., High Holborn, send us flowers of BORDER PANSIES most varied in colour, very sweet, and of good size. They represent an excellent strain, to which the title "International" has been applied.

— MESSRS. WILLIAMS, BROTHERS & Co. have sent us a sample box of their PLANT AND FLOWER SUPPORTS which they are advertising, and we have no hesitation in saying that the different kinds would be very serviceable in greenhouses and gardens. They are made of wire of the requisite strength for the purpose, and have sliding loops for securing plants at desired heights. These supports are neat, light, durable, and amateurs and others who experience difficulty in procuring neat flower stakes would be pleased with a supply of these cheap and handy contrivances.

— MR. A. J. BALLHATCHETT, The Palace Gardens, Fulham, London, S.W., sends the following record of the CUMULATIVE AMOUNT OF FROST:—"Having just made up my meteorological register for the winter of 1885-6, I send you the following extract for publication, thinking it may be of interest to many readers of the *Journal of Horticulture*. At Fulham Palace, London, S.W., 106° of frost were registered here from October 6th (the first night of frost here) to December 31st, 1885; and 394° from January 1st to May 6th, 1886 (the last night of frost here), making a total of 500° for the winter of 1885-6. The sharpest night was that of January 7th, 1886, when 18° were registered."

— MR. F. ROEMER, Quedlinburg, Germany, sends us samples of some fine DOUBLE WALLFLOWERS, the blooms 2 inches in diameter, very full, and varying in colour from bright yellow to rich brown, reddish brown and crimson, the latter a peculiar tint, more like a Stock.

— THE schedule of the HULL CHRYSANTHEMUM SHOW announces that the third annual Exhibition will be held this year in the Artillery Barracks, Park Street, Hull, on Thursday and Friday, November 18th and 19th. The total value of the prizes this season has been increased by £30, one of the principal features of interest being the silver challenge vase (value 15 guineas) offered by G. Bohn, Esq., in the class for forty-eight cut blooms, which was won last year for the first time by Mr. D. Lindsay, gardener to Sir Thomas Edwards-Moss, Otterspool, Liverpool. It is offered on the same conditions as that at Kingston—namely, it must be won twice consecutively or three times altogether to become the exhibitor's property. In addition to the vase, prizes of £10, £8, £5, and £2 are offered in the same class. Two other silver challenge cups, value 10 and 8 guineas respectively, the former for a group of Chrysanthemums arranged for effect, and the other for the best tray (amateurs') in classes 22 and 23 for twelve blooms of incurved and twelve Japanese respectively. A piece of challenge plate is also presented by G. Bohn, Esq., in class 42, for a dessert table laid out for six persons, only Chrysanthemums with any kind of foliage to be used in its decoration. This is confined to ladies. In other classes there is also a good provision for competitors, and the prize list altogether is one of the most liberal issued. The Hon. Secretaries are Messrs. R. Falconer Jameson and William Hawsworth.

#### A SURREY GARDEN.

IN continuance of an admirable custom, the interesting garden at The Grange, Wallington, has, during the present week, been thrown open to all visitors by the proprietor, A. H. Smee, Esq., and some idea may be formed of how this privilege is valued by local residents and others from the fact that on Sunday afternoon last over 500 persons were admitted to the grounds. This time of year is the best that could be chosen for an inspection of The Grange garden, as it possesses a freshness that is most charming. The shrubberies are rich in choice varieties of Rhododendrons, White and Scarlet Thorns, Lilac, Laburnums, the double golden Gorse, and numbers of others, but the Thorns are especially beautiful, and afford

a delightful colouring in some of the picturesque vistas. At one point in particular, near the river Wandle, there is a plant of an exceedingly rich scarlet double variety which dips to the level of the water, and is vividly reflected. The shaded winding walks and dells, with their running streamlets, miniature waterfalls, and Fern-clad banks can be most thoroughly enjoyed on a warm afternoon or evening, and many visitors must experience a feeling of regret that gardens are not more frequently planned on a similar informal design.

There is a pretty display of Orchids in several houses, but the majority of those in flower are arranged in the Fern house, where they have a graceful effect. Numerous plants of *Cattleya Mossiae* are flowering now, and some very choice varieties are included in the collection, differing considerably in size and colour. One distinct form has the lip richly veined with crimson, running deeply into the throat, the gold marking usually present having nearly disappeared. Another variety, just the reverse of this, has the lip tinged with gold throughout, the crimson colour being chiefly confined to the sepals and petals; a third is nearly white with a faint tint of colour. There are also many intermediate gradations of more or less beauty, such, in fact, as would at one time have received names, but in many establishments this custom has now been very properly discontinued. *Cattleya Mendeli* is represented by numerous varieties. *Laelia purpurata* also adds much to the attractions of the house, together with *Cattleya gigas*, of which there are some stray plants. *Odontoglossum crispum* and *citrosimum* are well represented, the former by some excellent varieties, and the latter by good plants bearing graceful drooping racemes or panicles of flowers. The useful *Dendrobium thyrsiflorum* is in good condition with fine racemes of white and gold flowers, and pleases the general public more than any other Orchid. Of *Masdevallia Harryana* there are many plants and excellent varieties, *M. Veitchii* is very bright. The Humming Bird Orchid, *Masdevallia trochilus*, and the curious *M. coriacea* are also flowering. The orange red *Saccolabium curvifolium* attracts attention amongst the others owing to its distinct colour. The purple-lipped *Cirrha viridis*, the long-lasting *Lycaste Skinneri* and numbers of others serve to vary the display both in beauty and interest. Many ferneries of this kind might be suitably turned into Orchid show houses, for Orchids need the graceful foliage of Ferns to show them to the best advantage.

In other cool houses the general collection of *Masdevallias* is grown and thrive well under the coolest treatment, the house being most liberally ventilated at this time of year, and having extremely little heat at any other period. A plant of *M. Shuttleworthi* in a small 60-size pot has had twenty-four flowers of an excellent variety, but it is now past its best. With really useful species are included plants of such curiosities as *M. simulata*, *M. triaristella*, *M. Culex* and others. *Odontoglossums* are looking well, making vigorous growth, are evidently quite at home and apparently profiting by their sojourn out of doors last year. A curious fact is noticeable, however, with regard to the changeability of varieties under culture. A variety of *Odontoglossum crispum*, which flowered last year and was then found to be one of the best in the collection with large well-formed blooms, is flowering again now, but the blooms have come so small and imperfectly formed that if the precaution had not been adopted of marking the label previously, it would have been discarded as worthless. The plant is not a large one, and it is possible that it weakened itself last season by flowering freely, the result being the production of undersized flowers this year. Whatever be the cause, it shows how careful growers should be in condemning apparently bad varieties upon one season's trial. Two plants of *O. gloriosum* are bearing seed pods. One that has been either self-fertilised or crossed by the aid of bees has three long pods, the effect on the plant being seen in the shrivelling of the pseudo-bulbs. Another plant of the same species crossed with *O. crispum* has also a large pod and is suffering in a similar way. When experiments of this kind are undertaken with small plants amateurs must be prepared to lose them, and it is therefore dangerous to attempt them with valuable varieties, unless the experimenters are aware of the risk. In collections like that of Mr. Smee's, many interesting results might be obtained in hybridising, and it is well that amateurs are now paying more attention to the subject.

The Phalænopses are steadily improving since the plants have been suspended from the roof of the warm house over a shelf upon which small Ferns and other plants are growing, and from which a constant healthful moisture is arising. This practice has been adopted by several of the most successful cultivators. The pretty but seldom seen *Dendrobium mesochlorum* is flowering freely upon its slender stems, the small white flowers with their purple-tipped sepals and petals being most graceful. An unnamed *Dendrobium* in the way of *D. draconis* (*eburneum*), is flowering, but it seems distinct from that species in the longer lip, and in the sepals being tinged with yellow. These are only a few of the principal plants in flower, but there are many more advancing, and a collection which comprises over 700 species and varieties can never be wanting in interest, and under the care of Mr. Cummins the general health of the plants is all that could be wished.

#### CHRYSANTHEMUM SEGETUM CLOTH OF GOLD.

A HANDSOME variety of *Chrysanthemum segetum*, or possibly a hybrid between that and some other species, has been obtained by Mr. Robert Owen, Castle Hill, Maidenhead, and it seems likely to be such a useful addition to this race of plants that we give an illustration of the variety. The blooms sent to us were of great size, the florets thick, and the colour an extremely rich golden yellow.

Writing respecting this plant, Mr. Owen remarks—"The Chrysanthemum or Marguerite Cloth of Gold is a chance seedling. I planted three years ago every variety I thought worth cultivating—two or three plants of each—both of *C. frutescens* and the annual varieties. I saved the seed from each, and sowed it the following year (1884) in the open ground, and from the seedlings I selected four which I thought distinct, Cloth of Gold being one of these. The original plant in a 16-size pot is now in full bloom and ripening seed at the same time; it has been flowering since last summer. Cuttings strike very freely. I cut many flowers during winter and quantities during spring, and I am told it lasts quite a week in a cut state. The florets droop at sundown and in dull weather, but expand again during light days and bright weather. I have

Fig. 83.—*Chrysanthemum segetum* Cloth of Gold.

measured blooms 4 inches in diameter. The flower stems average a foot in length."

#### MR. WILLIAM BULL'S ORCHIDS.

It is impossible to imagine a more beautiful and tasteful floral display than that provided in Mr. W. Bull's nursery, King's Road, Chelsea, and, admirable as have been his previous exhibitions of Orchids, this season's production surpasses them in all points. Those who have a keen remembrance of visits in other years will scarcely think it possible to excel such charming displays, but it is an admitted fact by many who have made the comparison. This year greater numbers of species and varieties are represented, the flowers are more numerous, yet there is a sufficient proportion of graceful fresh green Ferns and Palms to soften the brightest tints and prevent the slightest approach to an undue preponderance of colour. The great charm is, however, found in the arrangement, which is free from all formality, the plants being disposed with that highest art which is concealed from the observer, and so natural do they appear either in groups or singly, that we could imagine them luxuriating in their native homes. Sticks and stakes, which are too frequently employed for

Orchids, are abjured in the Chelsea establishment, as in very few cases do the flowers need any artificial support, and the panicles or racemes, which naturally have a drooping or pendant habit, can only be seen to advantage in that position, for when rigidly secured they lose more than half their beauty. *Odontoglossum citrosmum*, for instance, which usually has its elegant panicles fixed to perpendicular sticks, is then deplorably formal; but when, as at Chelsea, the plants are suspended in baskets from the roof at intervals, the drooping flowers assume their natural appearance, and the species is seen as one of the most beautiful of the genus. Orchid flowers are in themselves so informal that everything associated with them and their surroundings must be similarly informal, or the incongruity is at once noticeable; so that although it is necessary in cultivation to have the greater part of the plants in pots, but when being arranged for effect the pots should be concealed as far as possible. This point also has received careful attention in Mr. Bull's house of Orchids, and by the employment of Ferns, Selaginellas, and other suitable plants a delightfully varied undulating bank of greenery is formed from which the flowers peep forth in an irregular and most artistic manner. The central bed and side stages are margined with *Adiantums* and a deep fringe of *Panicum intermedium*, a pretty form with green-striped leaves, well adapted for work of this kind, and the paths are formed of dark material that has been found much better than anything light coloured, such as gravel or shells, which detracted from the appearance of the show. These points are mentioned to indicate that, however fine a collection may be grown, the success of an arrangement depends greatly upon attention to matters that the inexperienced might be apt to overlook.

The house devoted to this magnificent exhibition of Orchids is about 100 feet long, with a central bed, round which a path passes, and two side stages, and it would be difficult to estimate the number of plants employed or their aggregate value. The collection includes some of the choicest varieties of well-known species that could be obtained by importation or purchase, and it need scarcely be said that the plants are in first-rate health, for nothing short of this would be tolerated by such an experienced orchidist as Mr. Bull. Upon entering the attention is arrested by a grand bank of *Odontoglossum vexillarium*, an Orchid which many find difficult to grow, but which is a speciality at this nursery, and apparently grows as freely as the most easy. There are several fine varieties, such as bicolor with a white lip and rosy sepals and petals, tricolor similar, but with a yellow blotch at the base of the lip, and some highly coloured forms such as *rubrum*; but one of the most beautiful is that named *chelsoniense*, which has flowers of great size, excellent in form, with heavily marked dark rosy crimson lines radiating from the base of the lip. Throughout the house the plants of *Odontoglossum vexillarium* instantly attract attention, although the eye is too taken by the general effect that a visitor must pass round several times before he can particularise, and even then it seems irksome. Other *Odontoglossums*, such as the favourite *crispum*, *citrosmum*, the scarce, distinct *polyxanthum*, and *cirrhosum* are well represented, but the first two named are in the majority, the varieties differing greatly, but all are good, the crispums being especially noteworthy for their superb forms, the broad substantial petals, and sepals pure white or deeply tinted with rose and spotted. Of *O. citrosmum* varieties are seen with pure white flowers, and others with the lip tinted with various shades of rose, or with the petals spotted. *Odontoglossum nebulosum* is very noteworthy, the varieties *pardinum* and *punctatum* forming a beautiful pair, the former with large roundish spots lighter in the centre, and the latter freely dotted with small spots. The lovely little *Odontoglossum Cervantesi* and the floriferous *O. Rossi majus* are numerous, plants of the latter in small 60-size pots having fifteen to twenty flowers, abundantly proving its usefulness. *O. luteo-purpureum* is growing very strongly, one handsome plant bearing three long racemes of darkly coloured flowers. Many other charming *Odontoglossums* might be named, but another important genus demands a few words of praise.

Cattleyas and *Laelias* take a place amongst the most noble of the aristocratic family, and the Chelsea collection is remarkably rich in choice representatives of those magnificent Orchids. Looking along the banks on each side of the paths single specimens or little groups of *C. Mendeli* and *C. Mossii* in innumerable grand varieties are prominent. *Laelia purpurata* is equally numerous and varied, the superb form *Brysoniana* and others of equal beauty at once commanding attention. Of *Cattleya Mendeli*, a magnificent variety faces the path in front of the mirror at the end of the house, where, in company with some choice *Odontoglossums*, its intensely rich crimson lips are seen to the greatest advantage; it is one of the finest forms in cultivation, numerous as these are at the present time. The profuse *Cattleya Skinneri*, the fragrant yellow *C. citrina*, the elegant blush-tinted *C. Schilleriana*, the new and fast improving *C. Lawrenciana*, the attractive *C. Warneri*, the dwarf pretty *C. lobata*, the majestic *C. gigas*, and many others contribute materially to the beauty of the Exhibition.

A bare enumeration of the Orchids in flower would occupy considerable space, and we must confine these notes to a few references to the most remarkable plants, but it will be difficult to do justice to them in a hurried description. *Cymbidium Lowianum* is in excellent condition, a number of large vigorous plants being included, and some distinct varieties such as *atro-purpureum*, which has extremely dark richly coloured lips, a striking contrast with the ordinary forms, and *albo-sanguineum*, in which the throat of the lip is pure white, and the upper portion deep red. Delightful flashes of colour are furnished by the bright orange scarlet *Epidendrum vitellinum majus*, and crimson shades are supplied by *Masdevallias Harryana* and *Lindenii*, the varieties of the former being particularly handsome. *Cypripedium ciliolare* and *C. Lawrencianum* stand out prominently amongst the "Ladies' Slipper"

Orchids. The useful *Oncidium concolor* is freely employed with excellent results, and the new *Oncidium Jonesianum* is bearing its handsomely spotted flowers, *Oncidium macranthum*, and *O. bastiferum* with clear yellow petals and brown sepals are also notable. With these must be mentioned the extraordinary Butterfly Orchids, *Oncidium Papilio* and *Kramerii* with their golden and reddish brown flowers floating in the air on slender stems, almost startling in their resemblance to the gaily coloured butterflies of tropical regions. These mimicking Orchids take the popular attention far more than the most brilliantly coloured species, and they add greatly to the interest of a collection. *Anguloa Clowesi*, *Sohralia macrantha*, *Thunias*, *Aerides*, *Phalaenopsis*, *Dendrobium*, such as *thyriflorum*, *Jamesianum*, and *infundibulum*, with innumerable others, unite to form an exhibition which is worthy of a visit from all admirers of Orchids, or who appreciate a tasteful floral effect.

### ROSE SHOW FIXTURES, 1886.

FOR the guidance of those Societies which have not as yet fixed the dates of their exhibitions we publish the following list of Rose Shows arranged to be held during the coming season.

- Bagshot and Windlesham Rose Society, at Bagshot, Tuesday, June 29th.  
 Diss Horticultural Society, at Diss, and the Canterbury and Kent Rose Society, at Canterbury, Tuesday, June 29th.  
 Farningham Rose and Horticultural Society, at Farningham, Wednesday, June 30th.  
 Croydon Horticultural Society, at Croydon, Wednesday, June 30th.  
 Reigate Rose Association, at Reigate, Thursday, July 1st.  
 Tunbridge Wells Horticultural Society, at Tunbridge Wells, Friday, July 2nd.  
 Brockham Rose Association, at Dorking, Saturday, July 3rd.  
 Eltham Rose and Horticultural Society, at Eltham, Saturday, July 3rd.  
 Crystal Palace Rose Show, Saturday, July 3rd.  
 National Rose Society, at South Kensington, Tuesday, July 6th.  
 Cardiff Rose Society, at Cardiff, Wednesday, July 7th.  
 Sutton Amateur Rose Society, at Sutton, Wednesday, July 7th.  
 Oxford Rose Show, Wednesday, July 7th.  
 Ealing, Acton, and Hanwell Horticultural Society, at Ealing, Wednesday, July 7th.  
 Bath Floral Fête and Band Committee, at Bath, Thursday, July 8th.  
 Ipswich and East of England Horticultural Society, at Ipswich, Thursday, July 8th.  
 Hitchin Rose Society, at Hitchin, Thursday, July 8th.  
 Hereford and West of England Rose Society, at Hereford, Friday, July 9th.  
 Maidstone Rose Club, at Maidstone, Friday, July 9th.  
 Cray Valley and Sidcup Horticultural Society, at Frognaal, Saturday, July 10th.  
 Wirral Rose Society, at Birkenhead, Saturday, July 10th.

### PROPAGATION OF TUBEROUS BEGONIAS.

THE Tuberous-rooted Begonias have, during the past few years, been making steady progress in the flower garden, and they are admitted by all who have attempted their culture in open beds during the summer and autumn months to be unique. It is a step, too, I feel sure, in the right direction, as by its adoption we see less of the vivid glare which has too often occupied the greater part of many summer beds. The formality of the design, too, is somewhat avoided, for happily we cannot pinch and pick, in other words, mutilate the Begonia so as to form it into any set design, so that it must be allowed to grow naturally to see it in perfection. When thus seen they may be said to constitute one of the most enjoyable floral arrangements which any garden can contain. The Begonia delights in a free, light, sandy, and fertile loam, and commences flowering almost from the first joint, continuing successively to produce its varied coloured blossoms till checked by autumn frost. Those who desire an attractive bed should never select the huge-flowered varieties, which are better for pots in the conservatory, or for exhibition.

The simplest means of obtaining a stock of Begonias is by seed, and which is easily managed, provided the following simple rules be adhered to. Firstly, the soil should be in good order when the seed is sown, or it may be opened on the bench or the floor of a dry shed, sufficiently dry in fact to pass through a sieve of three-eighths of an inch mesh without clogging, then three parts fill thoroughly drained pots, making the surface even and very firm, sprinkle a little white sand on this to mark where the seed falls, and thus avoid sowing too thickly, in which case many decay. Secondly, after sowing the seed scatter very lightly from a wire gauze sieve (or if this be not at hand the fine rose of a watering can I have found an excellent substitute) a little dry silver sand, so as to barely cover the seeds, after which plunge away in slight bottom heat—say about 60°, and cover the pots with a piece of glass. If the soil is in the right state they will not require watering for three or four days, keeping the pots at this stage quite dark, as by so doing watering is dispensed with, for after all the watering pot is the greatest enemy in the raising of Begonias from seed. The seed should be barely covered, and in fact some growers do not cover it at all. I have frequently adopted the same practice with equal success; but knowing the great losses attending the injudicious use of the watering pot, I nearly always cover it as above described, and thus avoid the seed being displaced when vegetating, which is sure to end fatally. Watering, I may observe, should never be done till the seedlings have their second leaf. What appears to suit the

seed best, and which falls very lightly on them, is the spray from the syringe given at a distance, and settling on the seed pots much as a thick misty rain. Thirdly, when the seedlings are up always avoid incessant sprinklings over the foliage. This is highly detrimental and often fatal to them, consequent upon their extreme succulent nature at this time. When they have reached the second and third leaf a lighter position near the glass will suit them, where they will soon make headway and be ready for planting in small nursery trial beds, having been thoroughly hardened previously, and of course pricked off into boxes or pans in the usual way of small seedlings.

The other means of increasing this section of Begonias to which I shall refer is by cuttings. It is by this means that the best forms of the singles and all the doubles are propagated, and which can only be performed where good strong tubers exist, capable of throwing up several strong growths. In adopting this method, and to avoid overcrowding and the consequent damping off, the cuttings should be inserted singly in small thumb-pots, using rough fibrous leaf soil and plenty of sharp grit, passing all through a half-inch sieve, well rubbing the fibre through. The soil ready, the next thing is the cuttings, and this is how I get them:—Taking half a dozen large 60-pots and as many labels, I select the strongest and forwardest plants, having cuttings 3 or 4 inches long. These I detach with a sharp knife close to the tuber, securing, where possible, a slice of bark and a heel as well to the cutting. Such cuttings as these are almost sure to form roots readily with judicious management. Those, however, that cannot be obtained in this way should be taken off as close to the tuber as possible, and where the naturally succulent growth is somewhat firmer. These latter, though by no means difficult to root, require the greater care. Having filled half a dozen pots, take them to the potting shed, potting them singly, and labelling each one, defining singles from doubles by placing the first letter of each word on the label as the case may require. When all are complete, plunge them into bottom heat of 60° or 65°, but on no account water them for the first two or three days. It is the orthodox practice to water cuttings newly inserted at once, and generally speaking, with softwooded plants it is the right way to prevent flagging. The Begonia, however, is extremely succulent, the stems being capable of sustaining themselves for days, even in a cutting state, without water, and even longer, provided they are plunged in damp cocoa fibre and kept comparatively close. By the third or fourth day the cuttings will have begun to heal, in other words, be in the first stage of forming a callus. When this stage is passed the danger is considerably lessened, and presuming the soil is dry on account of the heat in the propagating house, a good watering may be given, leaving the lights off for three or four hours till the foliage is quite dry. This watering under the circumstances I have described should last them five or six days, according to the weather at the time, after which all that are dry are best taken out singly and watered, for it is not an easy matter to direct a volume of water to any particular pot in the propagating case without wetting others. By taking them singly as described, each may be watered effectually without damping a leaf, a thing to be desired when propagating these Begonias from cuttings. After the tenth day air may be admitted by degrees, according to the progress of the cuttings, thus keeping them short and of sturdy growth, as, by being essentially greenhouse plants, they soon become drawn and weakly if kept too warm or too close. In three weeks or a month the majority will be well rooted, and having been exposed in the house for a few days may be repotted into small 48-sized pots. These will carry them through the first season, one of the chief points being to secure a sound tuber by the autumn.—J. H. E.

### HORTICULTURAL SHOWS.

THE following are the dates of the principal Shows to be held during June and July this year. The great event of the season will no doubt be the provincial Show of the Royal Horticultural Society at Liverpool at the end of June.

#### JUNE.

- 8th.—Royal Horticultural Society Committee meetings; Orchid Exhibition.  
 9th.—Royal Botanic Society second Summer Show.  
 11th to 18th.—Manchester National Horticultural Exhibition, Old Trafford.  
 17th and 18th.—Brentwood.  
 22nd.—Royal Horticultural Society Committee meetings and Pelargonium Show.  
 23rd and 25th.—York Floral Fête.  
 29th to July 5th.—Royal Horticultural Society Provincial Show at Liverpool.  
 30th.—Croydon Horticultural Show.  
 30th.—Royal Botanic Society's Evening Fête.

### CULTIVATED VIOLETS.

(Continued from page 421.)

VIOLETS have one characteristic in common—viz., they need similar situation, soil, and treatment during the preparatory or growing season; albeit, the arrangement of the plants in the summer must accord with the purpose they are intended for in the winter. If to flower where grown the plants must be disposed in such manner as will best admit of their being covered with frames, accelerate the gathering of the flowers, and facilitate affording protection in severe weather. Though a native of this and other countries where the winters are severe, the fact of culture,

and especially high culture, rendering plants, otherwise hardy, less so, cannot be too strongly impressed on the minds of Violet growers.

*Situation.*—Although the Violet is naturally a shade-loving plant, it is culturally so enlarged in its parts that it requires full exposure to light and air for the solidification of the growth as made in order to obtain plenty of flowers in due season. The situation should be open, exposed to the sun from its rising to setting, but if there is the shelter of low shrubs or hedges so high as to break the force of winds from the south-west to south-east following the course of the sun, it will be an advantage. Walled gardens, and spaces enclosed by hedges, are eligible, only the plants are kept at such distance from the walls and fences as to be beyond reach of the hot and parching influence of the heat they reflect and radiate in hot weather, and are kept from the shade occasioned by the walls or hedges. The warmth of a south, and of an east and west border, is of great advantage in winter, and in spring in accelerating the flowering and in securing immunity from cold, but the cultivator must be prepared to supply moisture to plants so located corresponding to the increased necessity, or the result will be an enfeebled plant. A north border is, of course, the place to plant with a view of having Violets late, but even in this the danger is that the soil may become dry in the immediate vicinity of the wall or hedge, retarding the growth of the plants in summer so that the gathering flowers in late spring is most precarious and unsatisfactory. All things considered, a situation exposed to full sun and air is much the best for Violets.

*Soil.*—Any kind of soil in good heart will grow Violets. The best is a good hazel or yellow loam, sufficiently porous as to allow of the free percolation of water through it. Wet soil is of no use for them until it is drained efficiently, and light soil is equally unsuitable until it is made cooler and more retentive of moisture. Heavy soil may be improved by an application of burnt clay, ashes, sand, and old mortar rubbish, soil from potting benches, rubbish heaps (woody matter should be charred), and road scrapings. The practice of throwing up clay soils in ridges, either to summer sun or winter frost, has a decidedly advantageous ameliorating effect, and turning it over on dry frosty mornings aids the process considerably. Light soils will be permanently improved by a good marling or dressing of clay, it being exposed to frost when it will fall on thawing, or baked in the sun it will fall with rain; in any case it should be broken into as small particles as possible. A dressing of chalk is useful on light soils, and so is lime, especially in the case of soil of a peaty or alluvial nature, one bushel per rod (30½ square yards) being a proper dressing. As the tendency of all solid matter is to sink deeper in the soil the materials named should always be applied on the surface, and only mixed with the top spit of the ground by forking, any deep digging or trenching having previously been done. If trenching be necessary care should be taken not to bring up much of the stubborn pan to the surface, as it is poor and sterile, and of no use to Violets or any plant until it becomes ameliorated and enriched by atmospheric influences. It is better to break up the pan and leave it loose at the bottom of the trenching. Ground in good heart, having been well manured for previous crops, and those not being of an unusually exhaustive nature, will need very little, if indeed any manure. If poor, a good dressing of manure is essential, and it should be decayed, as fresh manure keeps the soil too open and induces a rank growth in the plants. The manure should not be buried deeply, but pointed in with a fork only. Ordinary soil will have all Violets need in a dressing of ordinary manure or leaf soil, merely pointed in prior to planting. They like a porous well-worked soil.

*Arranging the Ground for Plants.*—For the large-growing kinds the ground is best disposed in ridges similar to Potatoes 18 inches apart, the ridge being rounded and about 4 inches high. The medium-growing sorts should have the ridges 15 inches apart and 3 inches high; and lesser sorts 12 inches, with a ridge of a couple of inches high. The object of these ridges is to keep the plants well up to allow the leaves to fall away from the crowns and develop laterally, securing a maximum of value from light, air, and the free percolation of water through the soil, with the certainty of its being kept from the crown or centre. The effect on the plants is to secure strong central crowns and check the tendency to lose the centre and form a quantity of side issues, which never quite flowers at all comparable with plants having strong centres. By this arrangement of the plants they are readily available for weeding, removing runners, and mulching, and if wanted covered with frames three rows of those at 18 inches distance will take a 4 feet 6 inches wide frame; three rows of those at 15 inches will be covered by a frame 4 feet wide; and four rows of those at 12 inches with a 4 feet wide frame, and to allow for facility of ventilating and gathering the flowers every fourth row of those at 18 and 15 inches respectively will need be omitted in planting, and every fifth row of those plants at 12 inches distance between the rows. If the rows that would be needed vacant in winter, presuming the rows remaining were covered with frames, can be utilised for growing plants in summer to plant in frames or pits it will be an advantageous occupation of the ground until then; but if the plants are not so required it will be a sheer waste of soil and labour to occupy the space with plants in summer that must be cleared off in autumn, and the spaces kept clear will much facilitate cultural operations. In the case of the plants not being intended to be covered with frames it will much assist the general routine work to leave out every fourth row of those at 18 inches and 15 inches, and every fifth row of those with the rows 12 inches apart. The distance of the plants in the rows should be respectively 15 inches, 12 inches, and 9 inches, or 3 inches less than the rows are asunder.

On wet soil it is advisable to form beds 4 feet wide, with 2 feet alleys between, the soil being taken out of the alleys 6 inches deep, and spread evenly over the beds. The ridges should be drawn across the beds 18, 15,

and 12 inches apart, so as to accommodate the strong-growing plants at 15 inches distance apart in the rows, and the end plants 9 inches from the sides of the bed, the medium growers 12 inches asunder, and the end plants 6 inches from the sides of the beds, and the small growers 9 inches apart in the rows, and the end plants 6 inches from the side of the bed, which will give three, four, and five plants in the rows respectively. This arrangement admits of cultural operations being expeditiously performed, and of covering with frames 4 feet wide if deemed advisable. The beds should have the ends north and south.

*Planting.*—April or early May is the best time to plant. Select well-rooted runners or suckers of plants that have been grown outdoors. If they must be taken off plants that have been grown in frames the lights must have been off some time, so that the plants will be thoroughly hardened. Frame plants have their growth accelerated by the warmth the frames afford, and are to some extent debilitated so that they are not so good for outdoor plantings that are not to be so sheltered in future, as the plants have a tendency to complete their growth earlier and flower prematurely, which is not assuring of a full crop in spring. Hardy thinly grown plants afford the sturdiest and best rooted runners or suckers, and such only are advisable to yield a full supply of flowers in their proper season. Keep the plants as much as possible from the drying and injurious effects of the atmosphere, and plant with as little delay as possible. Plant so that the—taking out soil sufficient wide and deep to allow of the roots being spread out—growing point or centre is just level with the soil, and press the soil well about the roots, the plants having a slight dish around them to hold water, of which a good supply should be given at once to settle the soil about the roots. A showery time is the best to make fresh plantations of Violets, as they sooner become established, and the necessity of watering is decreased. Watering must be attended to daily if the weather be dry, and some pea sticks laid over the plants so as to break the fierce rays of powerful sun will materially assist the establishment of the plants. Some evergreen branches or tiffany shading will be a more effectual screen from sun, but such if employed must be removed at night so as to afford the plants the benefit of dew. If the weather be dull and the plants in proper condition shading will not be necessary, and getting them established without it is all the better.

*Cultural Requirements.*—Keep the plants free from weeds, which is best effected by stirring the soil frequently with a hoe, that not only keeps weeds effectually under, but a loose surface admits of the free absorption of moisture, and of the rapid passage of rain carrying air with it, and this is one of the greatest aids of rendering food available, and consequently its assimilation by the plants. Allowing weeds to get ahead until their removal by hand becomes a necessity causes increase of labour, depriving the plants of light, air, and moisture. Every weed robs the crop in many ways, and yet weeds are allowed to get tall and strong before the cultivator takes measures to eradicate them. The weeds have, then, taken more nutriment from the soil than the legitimate plants, and the latter have less food available for their use. They show this in the crop, for as the plant is nourished so is the resulting produce. Weedy plants are weak and drawn, cleanly plants are sturdy and well favoured; barrenness is the characteristic of one, floriferousness of the other.

*Firming the Soil.*—In four to six weeks the plants will have taken freely to the soil, having made some growth, and a good amount of roots. By the middle of June the soil, if properly attended to in hoeing, will be clean and loose, full of air and solar heat, and the plants growing freely. The plants must be kept in steady progressive growth, and this is best effected by firming the soil well about them, and thus giving greater resistance to the passage of the roots through the soil will multiply them. The ground should be dry at the surface when the soil is firmed. Press the soil with the feet, going all round the plants, and as near the neck as possible without injuring the leaves or collar. The whole of the ground should be well firmed, and this is an absolute necessity on light soil, and advisable on all, only heavy soil will be close enough of itself, though if clotty a good treading will be of benefit.—*VIOLA.*

(To be continued.)

## PLANTS AND THEIR DEFENCES.

A CONSTANT struggle for existence, the consequence of the enormous increase in the numbers of the individuals of almost every species, is the fate of nearly every organism, both animal and vegetable. Some have to sustain the attacks of others which are directly antagonistic to them, and which regard them as prey; in the case of others the struggle is rather one to live in the face of adverse conditions or peculiarities of environment, so that the different organisms are not directly hostile, but each affects its neighbour injuriously by adapting itself more readily to the changing surroundings, and so diminishing the other's power of obtaining nutriment, sunlight, or whatever other condition may be the object of their competition. Thus have been developed in the different competitors different features of their constitution—many perfecting powers of active assault, others facilities for active or passive defence. The last named is particularly the feature found in the vegetable kingdom. The want of locomotion prevents any aggressive movement of the individual, and hence success in the struggle can only be secured by more complete adaptation to environment than its competitors can show, or by protective mechanisms guarding the individual from the assaults of organisms inclined to prey upon it. These mechanisms exhibit very great variety, and their object often seems obscure till they are looked at in the light of the environment of the plant, the conditions of its life, and the enemies against which it has to contend. The specially exposed points of attack

are three: the succulent leaves and shoots or the attractive fruits are assailed by animals in search of food; the honey secreted by the flower to allure to it the particular insect adapted to bring about properly the process of fertilisation attracts also other insects whose presence is useless for such purpose, and which therefore are only robbers; while the fertilising pollen is itself the object of desire on the part of others which are equally unable to apply it to its legitimate purpose.

The protective mechanisms of plants, therefore, so far as they are directed against aggressive animals, are to be looked for mainly in the neighbourhood of the young growing parts or the reproductive organs. Not exclusively, however, but generally the older vegetative parts are defended by their own inherent qualities, such as their hardness or wiriness, which keep them from being suitable for the food of their assailants. Such young growing parts in many plants, particularly those growing in exposed regions, are plentifully supplied with thorns, spines, or prickles, rendering them in many cases extremely formidable. The thorns or prickles may be produced on almost all the vegetative organs, and may be merely epidermal structures, or much stronger in composition, containing considerable developments of woody tissue. These thorny plants are most noteworthy in desert countries, some that are met with there, notably the so-called "Wait-a-bit" Thorn of Africa, having spines of immense length, and being quite impenetrable by man or beast. Cases are not of infrequent occurrence where even the lion himself is a considerable sufferer by coming into collision with this plant. So great is the development of the thorny character in this region that Grisebach connects it particularly with desert exposure and scarcity of vegetation. Nor are thorny plants by any means confined to such regions—on our own heaths the Gorse is a familiar plant, and one sufficiently formidable to passers-by; while other spiny Leguminosæ, as the Rest-harrow (*Ononis spinosa*), are not infrequent by the wayside. A further peculiarity may be noted in connection with these plants; often the thorns do not occur above the point which is assailable by the animal in its search for food; while, when the shoot has outlived its period of succulent condition, and its tissues have become hard and dry, the thorns do not persist, being much more numerous when the part is young.

Nor is this spiny habit confined to shrubs or trees. The Cactuses, which are so remarkable a feature of the vegetation of America, are equally well protected. Their surfaces show great variety of development in this particular: some have small groups of thick rigid spines, others long flexible needles of intense sharpness, penetrating easily the skin of the assailant, and almost impossible to extract.

More formidable defences even than thorns or prickles are found in the varieties of stinging hairs borne so plentifully on the leaves of many plants. These are represented in England by the two species of Stinging Nettle, which are, as everyone knows, capable of producing considerable discomfort to the unwary person who handles them. These are, however, not worth mentioning by the side of many of their tropical relations. The structure of the hair in all these is similar: a mass of cells forms a kind of swollen cushion below; on this is seated the long tapering hair, which ends in a somewhat recurved point or hook. The walls of the upper part of the hair are very strongly silicified, and are, consequently, easily ruptured. Lower down there is but little silica. When touched or rubbed by the hand, the pressure drives the hair downward; at the same time the brittle hook penetrates the skin and breaks off. The downward pressure forces out from the broken hair a fluid of intensely acrid nature, which, on entering the wound made by the point, sets up more or less severe inflammation. The fluid is generally conjectured to be formic acid—a view based on the fact that this acid can be obtained from the Nettle plant by suitable means.

While the English representatives of this group of plants are sufficiently formidable to careless intruders, some of their connections in other parts of the globe are distinctly dangerous. A traveller in Australia describes a specimen of *Urtica gigas* in the following terms:—"A specimen seen by Sir W. McArthur, still in full vigour, rises from its base by a series of buttresses of singularly regular outline, gradually tapering, without a branch, to a height of 120 to 140 feet. The trunk then divides into a regularly formed, wide-spreading head, which excites admiration from its extraordinary size. But the ordinary elevation of this tree is 25 to 50 feet, with a circumference of 12 to 20 feet. The leaves, when young and in vigorous growth, attain a breadth of 12 to 15 inches, and are of a beautiful dark-green colour. As may be expected, the poisonous fluid secreted from the foliage is very powerful, particularly in the younger leaves, and their sting is exceedingly virulent, producing great suffering, not unattended with danger. It is found in the northern part of New South Wales, and is a great impediment to the traveller." An Indian species (*Urtica* or *Laportea crenulata*) is equally obnoxious. It has rather large leaves, round which numerous small stinging hairs are placed. At certain seasons it emits when bruised so irritating an aroma as to cause a copious flow of saliva and mucus from the nose and eyes for many hours, while violent fevers have been caused by the fluid poured out from its ruptured hairs. *Urtica urentissima*, a Timor species, which is known to the natives by the significant appellation of "devil's leaf," has been known to produce effects so violent as to last twelve months, and has in some cases even caused death. *Malpighia urens* bears on its leaves hairs  $1\frac{1}{2}$  inch long, which are pressed flat along the surface. These act very similarly to those of *Urtica*.

The Loasææ, or Chili Nettles, exhibit similar defences, their power of stinging being very severe.

Other plants are protected also by hairs, which play rather a mechanical than a chemical part. Such are various species of *Deutzia*,

particularly *D. scabra*, which bears on its leaves numerous star-shaped hairs whose walls are permeated with silica.

Besides these defences, which are chiefly mechanical, though in the case of the Nettle a secretion acting chemically plays an important part in their behaviour, many plants are protected by chemical means alone. This is seen chiefly, though by no means exclusively, in the case of flowers and fruit. The plant secretes in different parts, or it may be throughout its system, a juice which may be poisonous, or acrid, or harmless in effect, but very unpleasant to its assailant. Thus very many of the Solanaceous plants have poisonous fruit, as *Atropa Belladonna*, and some species of *Solanum*. The whole plant is charged with juice of great pungency in many of the Ranunculaceæ, *R. accleratus* causing sores if allowed to come into contact with a delicate mucous membrane such as that of the mouth. Parts of the Aconite (*A. Napellus*) are intensely poisonous, while the seeds of *Strychnos Nux-vomica* yield the well-known drug strychnine. Others have a latex or juice which is intensely bitter and unpleasant to the taste, as the different species of Spurge (*Euphorbia*), the Dandelion, the wild Lettuce, different species of Poppy, and many others. An acrid juice is to be met with in many Cruciferae, as the Mustard and the Radish. The aromatic Umbelliferae, also, are protected in this way from many of their enemies, the peculiar flavour which they possess being very unpalatable to many birds which are attracted by their fruits. Other plants pour out resinous and other sticky secretions which serve the same purpose. Some others are protected by the possession of a very foetid odour, much resembling putrefying animal matter, though this has probably been developed to attract the carrion-loving flies which secure cross-fertilisation of the plants. Such are *Arum Dracunculæ* and *Stapelia*, the latter a genus of *Asclepiadaceæ*.

A very different kind of defence against intruders is found in a Sumatran parasite, *Hydriophyllum formicarum*. This plant, instead of developing special weapons of its own, attracts to itself a colony of ants whose sting is very severe. These resent very effectually the attacks of animals inimical to the plant. It is described as parasitic on trees in the form of a large irregular tuber, fastening itself to them by fibrous roots, and throwing out several branches above. The tuber is generally inhabited by ants, and is hollowed out by them into numerous winding passages, which frequently extend a good way along the branches also, giving them the appearance of being fistular. A similar arrangement is found in *Acacia sphaerocephala*, but a more elaborate one, as the plant not only serves as a habitation for the ants, but develops certain organs to attract them to it. The stem and branches are furnished with very large thorns, which are set along them in pairs. The thorns are enormously swollen at their bases, which are hollow, and in these swellings the nests of the ants are found, the magnitude of the enlargement being no doubt caused by the irritation of the insects. At the base of each pair of thorns, about midway between the two, is found a large nectar-secreting gland, which is very active. The leaves of the plant are pinnate, and on the leaflets are numerous small pear-shaped glands, consisting of delicate masses of cells containing an oily secretion. *Cecropia* is also protected in the same way; its stem is hollow and contains the nests of the ants. As in the case of the *Acacia*, glandular structures are present, which attract the ants and afford them food. Schomburgk describes a plant belonging to the order Polygonaceæ (*Triplaris Schomburgkiana*), a native of Guiana, as having its trunk and branches hollow between the nodes, and serving as the habitation of venomous ants. He also mentions an Orchid (*Schomburgkia tibicinis*), which, he says, has pseudo-bulbs arising from creeping root-stocks. These have a small hole at their base, and ants and other insects construct their nests therein.

Turning more especially to the reproductive organs of plants, we find them attractive to intruders, not only on account of their own palatability or succulence, but as providing two especial delicacies much sought after by the insect world—honey or nectar, and pollen. The object of the secretion of the former is to secure the due transference of the latter from the stamen of one flower to the pistil of another, and this is effected in most cases by some particular insect. The invasion of others would hence lead to loss of honey or pollen, or both, without securing the end aimed at. It is natural, therefore, to expect to find many contrivances to secure the secretion to the appropriate insect, and an almost infinite variety is found, some mechanical, others chemical, others partaking of the nature of both. The enemies most guarded against are those insects which we have seen in some other plants especially courted—ants. In assailing the plant they must usually ascend the stem from the ground, and many and various are the pitfalls placed in their way. In the Teale, the leaves, arranged in pairs along the stem, have their bases attached to it and to one another, forming deep cups, which are filled with water, thus presenting an obstacle to their ascent. The leaves of the Pine Apple are arranged to bring about the same result. Some plants are surrounded in their growth by water, as many of the Polygonaceæ. In *P. amphibium*, which grows sometimes in water and sometimes on land, and has two characteristic forms accordingly, the land form has developed round the flower-stalks a number of sticky glands, while the water form has nothing of the sort. The two forms are protected from the ants, but by different means. Silene, the Catchfly, and *Circea*, the Enchanter's Nightshade, also are examples of plants furnished with sticky glands. *Lactuca*, the wild Lettuce, emits a milky juice on being assailed by them. Other plants, as some varieties of the Willow, have very slippery flower-stalks, which the ants cannot pass along. The forms of the flower, too, lend themselves to protective purposes: thus *Antirrhinum* and *Linaria* have a close-shutting corolla, which they cannot enter; *Cobæa* is furnished with free hairs growing on the corolla, which block the way to the nectar, and which are insurmountable by the insects. Where such means are not found, in some

cases a counter-attraction is provided to draw the unwelcome visitors to parts where their attention will be harmless: thus *Impatiens* has honey-glands on the leaves which are said to stop the ants on their way to the flower.

Other insects than ants are also to be guarded against. Many flowers are capable of fertilisation by more than one species of insect, but others are especially adapted only to one kind. In these the form of the flower, while affording facilities for the proper insect to receive its pollen upon the proper region of its body, also presents obstacles to others which would be useless. The peculiar construction of the corolla in such cases serves as a protection to both nectar and pollen. This may be carried still further, access to the honey by other than the appropriate channel being hindered by chemical means. An instance of this is seen in the Alpine varieties of the *Aconite*, which are adapted for fertilisation by bees. Instead of the insect inserting its proboscis into the flower from the front, so as to make it pass the stamens and pistil, one bee (*Bombus mastrucatus*) bites a hole in the back of the hood formed by the sepals, and abstracts the honey. The white variety of the flower is unprotected against the theft, but the other, blue in colour, has a nauseous, bitter taste, and so is let alone.

Besides meeting the attacks of animals in these different ways, plants have to cope with other dangers, and require for these another system of defences, which are more associated with peculiarities of environment. They are assailed continually by varying conditions of climate and temperature, and have in many cases very curious modifications of structure and habit to correspond with these. A danger that threatens most plants, except in a few regions of the world, is that of having their pollen injured by rain. To meet this many varieties of form of corolla have been developed. Many have a long narrow tubular shape, the claws of the petals cohering together, while the free limbs can curve outwards in fine weather, but arch over the tube when wet. Others have a campanulate form, with the base of the bell upwards, so that rain falling on the flower cannot get near the stamens, but is shot off as by a roof. In others the stamens are covered over by development of another part of the flower, as in the *Iris*; the filament of the stamen, too, may be broad, and bear the anther on its under surface, as in the *Naiadaceæ*. It is rather curious that flowers that produce large quantities of pollen have not such defences against this danger as those which form but little, while the most complete adaptations are found in the cases of plants that inhabit damp climates.

Many flowers are defended by habit rather than structure. In wet weather they do not open their corollas at all, and not a few, even in fine weather, keep open for a very little while, only a few hours in many cases.

Besides rain, other meteorological conditions are fraught with danger. One of the most commonly occurring is frost; and allied to this is the loss of heat by radiation during the night. The power of resistance to these conditions varies very much, but in many whose constitution makes them peculiarly susceptible to damage thereby there has been developed the so-called power of sleep. The term is no doubt a misnomer, but it has been adopted and associated with certain well-defined movements which the leaves of the plants perform at the close and at the beginning of day. The movements differ very greatly with different plants, but they bring about such a position of the leaves as will protect the upper surface from radiation. Some of them are of a very complex nature, particularly those shown by certain of the *Leguminosæ*, which have pinnate leaves. It is in this natural order that the property of sleep is most prevalent, certain of the *Oxalidaceæ* and their allies coming next to them.

A similar mechanism protects very many plants from excess of sunlight, which is injurious to the chlorophyll. In bright sunshine the leaves assume a position which has been called "diurnal sleep." In it they present their edges and not their faces to the light. In other leaves the chlorophyll corpuscles themselves move, taking up a position on the lateral walls of the cells rather than on the front ones, or so placing themselves that their profile and not their surface is exposed to the sun. In some of the *Algæ*, as *Mesocarpus* and *Vaucheria*, this sensitiveness is seen.

Other protective devices may be seen by studying the adaptations of plants to their conditions of life. Thus the leaves of submerged plants are preserved from being broken by the currents of water by being minutely sub-divided, so that they adapt themselves easily to the motion, and do not oppose a resistance. Desert plants are protected from drought by the development of a succulent habit. Aërial parts of plants, again, are protected in many cases from becoming moistened by water by a deposition in the cuticular layers of the epidermis of varying amounts of wax or resin.—(*Nature*.)

#### NOTES ON HERBACEOUS PLANTS.

**DORONICUMS.**—There are no more showy herbaceous plants than the *Doronicums* at the present time, with their masses of green foliage and bright yellow flowers. They flower from the beginning of April far into the summer, and make our herbaceous border look very gay. *D. austriacum* is very pretty, and should be in every collection of herbaceous plants; it generally throws up its flowers to the height of 2 feet. *D. caucasicum* is also a very useful species, although not such a bright yellow as *D. austriacum*. *D. plantagineum excelsum* is one of the best *Doronicums* with its fine bright yellow flowers.

**GENTIANAS.**—When looking over the herbaceous borders the other day I was greatly struck by the beauty of that very old-fashioned plant, the *Gentiana acaulis*, with its beautiful rich blue cup-shaped flowers, for there is scarcely any flower in cultivation that has such a rich blue colour. *G. acaulis alba* is a lovely variety with white flowers; *G. septemfida* is a

dwarf-growing species, with terminal heads of bright blue-bearded flowers; *G. Andrewsii* is a very showy species from North America, with deep blue purple flowers; *G. Burseri* is very attractive with its large yellow flowers with purple spots, not forgetting that little gem *G. verna*, with its brilliant blue flowers, about 2 or 3 inches high. Most of the *Gentianas* should be in every collection of hardy flowers of any pretension whatever, for they have a most distinctive and attractive appearance.

**DIELYTRA SPECTABILIS.**—At the present time this is very attractive on the herbaceous border. This well-known plant is generally esteemed, both for its usefulness for decorating our greenhouses and conservatories in the early spring, and for our herbaceous border in the early summer. *D. spectabilis alba*, although not generally so well known, is a very handsome variety with white flowers. *D. eximea* is a very pretty dwarf-growing species with drooping red flowers; it is very useful both for the rockery and border.—AN OUTSIDE FOREMAN.

#### ANOTHER NEW BOILER.

MESSRS. STANLEY & TODD'S horizontal "V" tubular boiler is represented in the annexed engravings, fig. 84 showing the elevation and fig. 85

Fig. 84.

the section of the apparatus. As is apparent, it consists of a series of V or wedge-shaped tubes horizontally arranged with water bars of the same shape, the tubes or ribs being further covered with a hood or water jacket. Provision is made for cleaning every part of the boiler, and, as it is in sections, any repairs that may be needed can be readily carried out. In

Fig. 85.

arranging the boiler for working brickwork is not required, but without a non-conducting covering there would of necessity be a considerable escape of heat; with it, little or none. Different sizes are made to heat from 500 to 10,000 feet of 4-inch piping. The action of the fire on the different parts is plainly seen, and there can be no doubt the boiler will answer its purpose well.

#### ROOTING THE HEADS OF LARGE CORDYLINES.

THOSE who confine the roots of these plants within certain sized pots have but a poor conception of the strength and rapidity with which they

grow when planted out in a prepared border. If two plants of *C. lineata*, or any other variety, are rooted together and grown on until they fill 10-inch pots with roots, and one is then planted out and the other confined to pot culture, there will be no comparison between their progress. The one planted out will in two or three years attain an enormous size with dark green, broad healthy foliage to the base, while the other will not have foliage half the size and colour. In fact, the appearance of the latter would indicate to all unfamiliar with the plants that they were totally different varieties.

The rapidity of the growth when planted out has been urged as a drawback rather than an advantage, for they soon become too large for structures of moderate size. This is very true, and in large high houses they soon lose their beauty and high decorative value when the stem for some feet at the base becomes bare. Amongst other large plants, such as Palms and Tree Ferns, where the stem is hidden from view, they are most pleasing when the head towers well above surrounding objects for furnishing the upper portion of the house. In such positions I have observed them most striking and beautiful; but, in many other instances—perhaps the majority, for very few have such positions for them—they would have been decidedly more effective if several feet of the stem could be removed and the head again inserted in the border.

These large heads can be rooted with as much certainty as the head of *Dracaena Cooperi*, *D. terminalis*, or any other variety. Those having large plants in the condition indicated above need not fear commencing operations, for large heads with bold foliage for more than 12 feet can be successfully rooted without losing a single leaf after they are severed from the stem. This is decidedly the best time of the year to commence, for in a few months the old roots and stem can be removed and the head with foliage hanging on the ground again planted in its place. When the head is to be rooted it is a good plan to strip off all the old lower foliage that would naturally turn yellow in a short time, so that the plant will be as long as possible before it is again too large for the house, or as a bare stem at the base. The stem for a distance of 14 or 18 inches below the foliage should be surrounded with sphagnum or other moss about 3 inches thick. Below this the stem should be cut fully half through and gradually ringed. It is useless to cut a small narrow nick, for the ring of bark removed should be fully an inch wide. The bark all round the stem must not be removed until a good number of roots has been formed, but gradually extended from time to time. The moss should be kept constantly moist by syringing, and roots will soon be induced to take possession of it. When a fair quantity has been made add more moss and lumps of fibry peat, so as to just keep them covered. After the formation of roots and the stem has been bound once or twice lumps of peat and cow manure may be used as a medium for them and the moss dispensed with. Some of the first roots formed will be stout and as thick as a quill. It will be observed that these have a great tendency to grow downwards, but directly they show signs of extending below the portion ringed the points should be taken off them with a sharp knife, which will induce the formation of fibre. It must be understood that a good mass of roots must be formed before the head is taken off, for where there is a large head of foliage 12 or 14 feet above the roots formed on the stem a good quantity are required to support it. The last head we removed was of the latter size, and a 22-inch pot was not large enough to hold the quantity of soil and roots about the stem. One thing is necessary, when a good quantity of soil has been bound round the stem the head must be supported from above to prevent it snapping. After abundance of roots has been formed, and it is decided to take off the head, it should be cut deep all round for a fortnight or three weeks before its removal to be certain that no support is drawn from the roots. This compels the extension of the roots rapidly in the material provided for them.

When the head is cut off it should be placed in a large pot or tub for a time, and removed, if possible, to some close shaded structure; if heat can be given all the better. This is not essential, but the head becomes established earlier than if left in the house in which it had been grown. When this cannot be done the plant, for such I may term it, should be heavily shaded and liberally syringed for about a fortnight. The plant need not be kept long in the pot or tub, for it will soon be thoroughly established, and may then be planted out in the position it previously occupied.

When plenty of roots have been formed before the head is severed from the stem this plant does not appear to be checked in the least. On the contrary, the foliage produced afterwards will be equally as large and strong as while the process of rooting was going on. When large finely developed heads of these ornamental plants, with their drooping leaves and Palm-like appearance, can be rooted with such certainty and simplicity there is no excuse for the bare unsightly specimens crowding up to the glass we are so accustomed to see.—SCIENTIA.

## THE ROSES AT SOUTH KENSINGTON.

MAY 25TH.

It is always a pleasure to see those reminders of the season which are brought forward at the May shows. The amateur finds that he is waking up to the fact that the time for which he has been long looking forward is at hand, when he hopes to go through his garden and see each morning some beauty expanding, or in the deepening twilight marks the peculiar loveliness that that time spreads over his favourite flower. It is true that these plants and blooms which he sees are not what he exactly wishes, he prefers those which are grown in the open; and while he gladly welcomes

these forerunners of the season, longs for something better still; he eagerly looks out to see if any new Roses are to be noticed, and wonders what their position will be in the exhibition season now close at hand.

Pot Roses have certainly altered their character during the last few years. The gigantic trees of former days have departed. Those giants with which Messrs. Paul & Son and Mr. C. Turner used to fight, like the gigantic troopers of Frederick the Great, no longer find favour; and however wonderful they were as proofs of unwearied industry and skill, they represented to the mass of Rose-growers the unattainable. It would never have been worth the trouble and expense for an amateur to grow these huge plants, whereas the smaller plants, with two or three dozen blooms, represent a species of culture to which, if so minded, he may with greater ease attain. Moreover, there is after all more real beauty in these smaller plants, for although carefully trained they have not the appearance of ever having what the larger plants had. Is it not possible, too, that as these huge plants have been left high and dry the competitors may increase in number? Formerly it was felt that with such competitors in the field it was hardly possible to do anything against them, whereas with these smaller plants the field is open to other growers. One at least has put in an appearance this year, and more we hope may follow.

Amongst the pot Roses (I do not mention the names of exhibitors, as those were given last week) were *Centifolia rosea*, excellently bloomed and evidently an excellent pot Rose. *Sunset* and *Perle des Jardins* were shown side by side, giving proofs of the points of similarity and also their real difference, the colour of the former being much deeper, a rich *Madame Falcot* sort of colour; it will probably be what is called a fine weather Rose. Some have thought that it will be too thin, but I hardly think it is open to this fault. *Comtesse de Camando*, a fine dark Rose let out in 1880 by Levêque, but which is not often seen on exhibition stands by reason (Mr. Geo. Paul being my informant) of its being a very late Rose. *White Baroness*, evidently a good pot Rose, liable, however, to the charge of being too thin; *Lord Frederick Cavendish*, undoubtedly a fine bright high-coloured flower; *Madame Eulalie Fontaine*, a very beautiful Rose, well formed, rich rosy crimson, with violet sheen, quite distinct; *Professeur Edouard Regel*, a bright *Duchesse de Caylus* sort of flower, and one likely to be very useful.

Amongst the cut Roses were *Madame Lefebvre Deplace*, bright pink, something of the build of *Madame Charles Crapelet*, with large fine petals, well imbricated, bright pink, with a beautiful glassy sheen over it. *Souvenir de Léon Gambetta*, pink, with deeper centre; *Francisca Reve*, a flower let out in 1883 by Schwartz, a bright cherry red, said to be very vigorous, and certainly with a rich perfume; it would appear to be one of those Roses which are overlooked in the crowd of distinguished strangers which visit our shores every year. *Prosper Langier*, another good Rose (one of *Eugène Verdier's* 1883 lot), a brighter *Maurice Bernardin*. One looked in vain for what I was very anxious to see, *Clara Cochet*, which is said to be the best that *Lacharme* has ever sent out, and the finest Hybrid Perpetual yet raised. When we consider what *Roses Lacharme* has sent out, and call to mind *Marie Baumann*, *Charles Lefebvre*, and other fine Hybrid Perpetuals, a Rose that is to beat all these must indeed be a marvel. That *Lacharme* thinks highly of it may be inferred from the fact that it was let out by him in dormant buds at 25 francs. Another Rose we wanted to see was the new American sport from *Catherine Mermet*, said to be pure white and the finest white Rose in existence. If it should be white, and of the build and substance of its revered parent, it will be a great acquisition.

Such, my masters, are a few of those beauties, that like the *hors d'œuvre*, may whet your appetite for the coming feast. Is it to be a full one or not? Various are the opinions formed. Some write of want of vigour, others of shoots going blind, while others are confident we are to have a Rose season at last. The late rains have done wonders, and, as we are hoping to get fine weather, I see no reason why we should not have a good one. We have not had the cold wave of May 20th to 24th, and we trust all fear on that score is at an end, and we may look hopefully forward to a good feast.—D., Deal.

## FIRM SOIL THE BEST.

In my opinion sufficient attention is not given to making all soil in which roots have to form firm. In potting plants the soil is often merely thrown into the pots, given a shake and perhaps a gentle press down, and potting is supposed to be finished. A large number of plants may be potted in a given time in this manner, but anyone who likes to note the result of this work will not, I think, be favourably impressed by it. There is no close rooting in soil of this kind, as those formed are long, rambling, and fibreless. If at any time the soil becomes slightly too wet it is a long time in gaining a proper condition, and in the meantime the plant has got into bad health. Altogether, there is nothing that will cause a plant to grow indifferently so soon as loose potting. When the soil is made firm, however, the case is quite different. The roots are short and robust; they branch in all directions, and the soil is always sweet and healthy. In potting to secure the best results the soil should always be made very firm. In dealing with small pots the soil can generally be pressed down firm with the fingers and thumbs, but when large pots are being filled a blunt stick should be used as a rammer. In the case of potting Heaths, Azaleas, and other hardwooded plants, great attention is generally given to make the soil exceedingly firm, and if it takes a firm soil to induce choice plants to succeed I am sure more common ones would pay handsomely for the same attention.

In potting Pines, or any kind of fruit, the same rule is generally

observed in making the soil firm, and nothing short of this would agree with them. Fruit borders are always best when very firm, and the most roots are to be found in those which are submitted to a great deal of treading during the year, and if a tree is in bad health with the roots in a loose soil nothing will improve it quicker than treading the soil down as firm as it is possible to make it.

Kitchen garden crops are also benefited by being grown in firm soil. Onions, when grown in loose material, never bulb well but form thick necks, and they come best when the soil is rolled immediately after sowing, and they are also benefited by treading them on each side of the rows during the early stages of their growth. Celery will seldom "bolt" or fail in very firm soil. It is an excellent remedy for clubbing in Cabbage, Cauliflower, and plants of this sort; and a fine soil is also one of the best means we know to keep off the grubs from the roots. We are as particular in having the soil trodden down firm amongst these, and also amongst Carrots, Parsnips, &c., as we are to hoe or weed them, and of all our ways of inducing plants to succeed none assist so well as firm soil everywhere.

Those who have not given this matter practical attention may be inclined to think that the looser the soil is for Carrots, Parsnips, Beetroot, Salsafy, and other deep-rooting plants, the longer and finer will the roots become; but this is a mistake, as in such soil they only fork and throw out side roots, whereas in firm soil they go straight down, are quite fibreless, and turn out beautiful and clean.—A KITCHEN GARDENER.

#### HARDY FRUIT GARDEN.

THE late spring kept back growth so much that we were much later than usual in beginning the early summer pruning. This pruning is done principally by nipping off the young growth with the finger and thumb, for which reason it is usually termed pinching, the leading shoot of each stem or branch being pinched to about 9 inches or a foot, and the side or lateral growth to three or four leaves from the base. No pinching should be done till the fruit is set and is swelling freely. If necessary there should also be some thinning of new growth as the pinching is done if the spurs are at all crowded, in order that light and air may act freely upon every part of the tree. A moderate crop of really fine fruits is infinitely preferable to a crowded one of small fruits, and that should be our aim in all we do in fruit culture. When the fruit is swelling the borders or soil in which the roots are established should have frequent soakings of sewage or other liquid manure. Preference is given to sewage because of the daily supply to be had from every household, whence it comes to hand in a perfectly safe condition for immediate use. This cannot be always said of manure prepared by mixing guano with water, for we have known the fruit spoiled and the trees half killed by an overdose of it. Do not forget to use sewage freely now among Strawberries, Raspberries, and all bush fruit, to which it is hardly possible to give too much of this valuable cheap fertiliser till the fruit begins to ripen. In doing this we should understand that we are working for future seasons as well as for the present one, the regular use of sewage during the season of active or rather lively growth tending to promote robust health, and thus to secure a full development of the crop of fruit, of foliage, branch, and bud. How can we rest content with anything short of this in fruit culture? Aim high, say we, and achieve much; also let every season mark some advance in knowledge, that golden knowledge only to be gained by experience and some improvement in practice. Pinching may be done at once to the young growth of Red and White Currants; see also that the leading shoots of Currants trained to walls or fences are made fast at once, or the growth may be broken off by the first storm of wind and rain. Pears, Plums, some Cherries, and Apricots should have full attention to all necessary pinching and training forthwith. Nip off the tips of leading shoots now, and at mid-summer you will have another good break both of leading and lateral growth. Disbud Peaches and Nectarines, keeping only enough stout lateral growth for the fruit crop of next year. This is a point of culture requiring sound judgment, the general tendency being to tie in too much wood, and crowded growth is generally undersized, and the foliage is liable to become infested by red spider in July and August. If your young trees are very robust encourage rather than check the growth. The space covered by such young trees in a couple of years is absolutely marvellous. The leading branches will attain a length of 6 or 8 feet in a single season. The lateral growth, too, will be so rampant that it will often have sub-laterals of not mere abortive growth, but really fine stout fruiting wood well set with triple buds. If you would have fine fruit you must have robust growth. How can you expect large fruit upon the straw-like wood so common to half-fed badly managed Peach trees? Keep the soil about the roots well stored with fertility. Keep the new growth sufficiently far apart to admit light and air among it freely. Keep the foliage clean by frequently bringing a keen eye, a willing hand, a stout arm, a good syringe, and plenty of clean water to bear upon it, especially upon the under side of the leaves. Above all things do not overcrop. Such a thing as crowded fruit in Peach and

Nectarine culture ought never to be seen; a fruit to each square foot of wall space would afford us a large number of fruit, and such fruit too! The sight of a full-grown tree covering, say, 300 square feet of wall with about that number of Peaches upon it, each fruit closely approaching the size of a cricket ball, is not like the Waltham Roses, "a thing to see once and dream of for ever," but a thing to try and copy in our own practice, a standard of excellence to follow, a worthy object of ambition, and remember it is a possibility that falls within the scope of most gardeners.

#### FRUIT FORCING.

**VINES.—Early House.**—When the Vines are cleared of the fruit give the inside borders a thorough supply of tepid liquid manure. This will help to plump the buds and encourage root-action so essential to activity of the laterals—the best preventive of premature ripening of the foliage. Keep the ventilators open constantly, even in cold weather a circulation should be insured. Syringe thoroughly to cleanse the foliage of dirt and insects, especially red spider, and repeat occasionally or as found necessary to keep the old or main leaves healthy. Fresh laterals will soon be produced, and cultivators should maintain an even growth all over the Vines, pinching the gross growths and encouraging the weak, keeping them clear of the principal leaves which nourish the buds at their base. The mulching or covering having been removed from the outside border, with just sufficient of the lighter part left to protect the roots, a good watering with liquid manure may be given, but the recent rains having been general this will only be needed where none has fallen. Avoid heavy mulchings, and nothing is better than a couple of inches depth of fresh stable manure.

**Second Early Houses.**—Vines started early in the year will have the Grapes well advanced in ripening. Maintain a circulation of warm, rather dry air constantly, increasing the ventilation early. Keep the floors, &c., well damped on hot days with a view to check excessive evaporation, allowing the temperature to fall to 60° or 65° at night, with sufficient ventilation and warmth in the pipes to prevent moisture condensing. If there is likely to be any want of finish allow the Vines time by giving as long a rest at night as possible. If there is any doubt about the roots lacking moisture examine the border, and, if found necessary, give a thorough soaking of water in the morning of a fine day, and when soaked in mulch with a little light material. This will probably be sufficient to keep the border moist until the Grapes are cut; if not, it must be repeated. Moderate moisture will be essential to the health of the foliage, hence damping the floors and stages must be resorted to occasionally, there not being any fear of its damaging ripe Grapes at this season only it be accompanied with air, besides the moisture will assist in keeping the Grapes; and to prevent colour being taken out of Hamburgs a double thickness of pilchard nets should be drawn over the roof lights. Allow a moderate extension of the laterals to encourage root-action, but keep gross laterals well in hand so as to cause an equal distribution of the sap. When ripe a minimum temperature of 60° will be sufficient.

**Midseason Houses.**—Vines in these will be in various stages according to the time of starting. Those that have stoned will be swelling the berries fast, and the borders should have a soaking of tepid water through a good surface mulching, or if the Vines are not very vigorous and carrying heavy crops liquid manure will be necessary. The drainage being good, the watering, whether with water or liquid manure, will need to be continued at fortnightly intervals until the Grapes are somewhat advanced in colouring, when it must be stopped, yet the border must not be allowed to become so dry as to affect the foliage injuriously. Have a little ventilation constantly at the apex, and ventilate freely in the early part of the day, closing early with sun heat and a genial condition of the atmosphere. Fire heat will only be necessary to secure 60° to 65° at night, and 70° to 75° by day, keeping through the day at 80° to 85°, and closing sufficiently early to run up to 90° or 95°. This will insure the berries swelling to a good size, and with a free circulation of air a good finish may be secured.

Grapes stoning should have a regular temperature of about 65° at night, admitting air in good time, so that any moisture will be dissipated before the sun shines powerfully upon the house. Allow a moderate lateral extension, but avoid overcrowding and feed with liquid manure or water through a good mulching at fortnightly intervals according to the requirements of the Vines.

**Early Muscat Houses.**—The fruit in these is now ripening. Maintain a dry condition of the atmosphere as compared with Black Hamburg houses, but avoid great aridity, or the foliage will fall a prey to red spider. Muscats require time to ripen and assume that amber colour so much prized. Being gross feeders, do not allow any lack of moisture in the borders, but feed well either with tepid liquid manure or tepid water through a rich surface mulching. The supply of water to the roots will in some measure compensate for the drier condition of the atmosphere. Maintain a circulation of air constantly, preventing the moisture condensing on the berries by sufficient warmth in the pipes to insure a changing atmosphere. Lateral extension is the best safeguard at this stage against shanking along with a steady temperature. Avoid sudden fluctuations and depressions. Keep the night temperature at 65° to 70°, 80° to 85° by day with a little sun, and 90° to 95° with it in full force. Ventilate early, and with the sun's increase be regulated, and so with its decline, reduce early, securing as long a day of ripening from sun heat as possible. The old leaves of Muscats are very liable to be scorched under sudden changes of atmosphere, particularly so after a dull cold period. In very bright weather a single thickness of tanned net should be drawn over the roof lights, which, without impeding too much light, will have

the desired effect, especially if air is given at night to prevent the condensation of moisture.

**Late Houses.**—The Grapes in these will now have flowered, or late varieties may still be in flower, in which case artificial impregnation must be resorted to, operating with Black Hamburg pollen. The late Hamburgs being now in flower will be eligible for this purpose. Allow the laterals to extend until the available space is fairly covered with foliage. Avoid overcrowding, especially of the principal leaves. Syringe after flowering to cleanse the bunches of the remains of the flowers, and set about thinning as soon as the berries are fairly swelling. Select tapering and medium-sized bunches, and thin well out, leaving the large-berried sorts about an inch apart, and others according to the sizes they are likely to ultimately attain, which must be left to the judgment of the grower. Late Grapes, however, should be thinned more severely than midseason varieties in order to admit of air having free access to the interior of the bunches, and the readier removal of decayed berries. Allow a good rise with sun heat after closing, closing at 80° to 85°, and rising to 90° or 95°. Ventilate early, or between 70° and 75°, and increase with the advancing sun heat. Leave a little ventilation at the top of the house at night to prevent excessive condensation. Syringe available surfaces in the morning, and again at closing time. An occasional sprinkling with liquid manure will do much to keep down red spider, and will contribute much to the health of the Vines. Surface dress inside borders with fresh horse droppings, little and often, as too much ammonia is calculated to injure the foliage. Give inside borders a thorough soaking with tepid water or liquid manure as may be considered necessary on account of the crops and vigour of the Vines. Outside borders may have a thin covering of open manure, but water will hardly be necessary, except where no rain has fallen.

**CUCUMBERS.**—Plants in houses that have been in bearing since the beginning of the year may be cleared out, and the house cleansed preparatory to planting with Melons for a late crop. If, however, the Cucumbers are still insufficiently supplied from pits or frames, and the Cucumbers being fairly healthy, they may be kept in fruiting some time longer by removing the surface soil with a small fork, and replacing with some lumpy loam, afterwards surfacing with decayed manure, giving a good soaking of tepid water, and afterwards following with liquid manure. Thin out the old growths, and encourage young in their place. Shade from powerful sun, syringe both ways in the morning and early afternoon, and damp well down before nightfall. Admit a little air at 75°, increasing with the advancing sun, keeping at 85° through the day with sun, and close early so as to run up to 90° or 95°. Fire heat need only be employed to prevent the night temperature falling below 60° to 65°, and to insure 70° to 75° in the daytime. Plants in pits and frames should be ventilated from 7.30 to 8 A.M., and in the hottest part of the day a slight shade from fierce sun will be beneficial, and keeping through the day at 85° to 90°, close at 85°, increasing 5° to 10° with sun heat. Keep them watered as required, about twice a week will be necessary in bright weather, and damp overhead on fine afternoons. Avoid overcrowding the foliage, thinning well, keeping up a succession of bearing wood, removing bad leaves, stopping one or two joints beyond the show of fruit, and avoid overcropping. If straight fruits are wanted place them in glasses or pieces of deal nailed together so as to form open-ended troughs about 3 inches wide.

**MELONS.**—Plants in flower should have a little air constantly, a free circulation on fine days, fertilising the blossoms as they become fully expanded; and when a sufficient number of about equal size are set upon a plant remove all the others and all flowers, three or four fruits being as many as a healthy plant can bring to a good size, overcropping being fatal to quality and very often of the fruit not arriving at maturity, but of ripening prematurely. Plants swelling their fruits should have liberal supplies of tepid liquid manure and additions made to the ridges or hillocks of fresh soil as the roots protrude, and it should be warm. Young plants in pits and frames with the shoots trained over the surface of the beds should be thinned out to four, two being taken to the front and the other to the back, keeping the laterals rubbed off to quite 6 inches from the stem, and pinching the main shoots when 12 to 15 inches from the sides of the pits or frames. The laterals will show fruit at the first or second joint, and the flowers being fully expanded impregnate them about noon on a fine day, leaving a little air on constantly to prevent the condensation of moisture on the flowers, a moist close atmosphere being fatal to a good set. Pinch out the point of the shoot one joint above the fruit at the time of impregnation, and after three or four fruits are set and swelling on a plant remove all other fruit and blossoms. Keep the laterals closely pinched, and thin them if likely to crowd the principal foliage. Afford weak liquid manure, but keep it from the foliage, and sprinkle the plants in the afternoon on fine days, closing about 3.30 to 4 P.M., or so early as to rise to 90° or 95°, and ventilate early in the day, or from 7.30 to 8 A.M., keeping through the day at 80° to 85° or 90°, and reduce the ventilation gradually. Keep a sharp look-out for aphides, and fumigate on two or three consecutive evenings moderately—an overdose doing great injury. Shade the following days slightly if the weather be bright, and always have the foliage dry when fumigating. If canker appear rub quicklime into the affected parts until they are dry, and repeat as occasion requires, being careful to keep water away from the collar. Red spider will not appear if the plants are kept properly moist.

#### PLANT HOUSES.

**Justicia calytricha.**—This is perhaps better known in gardens as *Justicia flavicoma*, and is undoubtedly the best and most useful yellow-flowering plant in cultivation for purposes of decoration during the winter

and spring. If pushed forward in autumn in a temperature of 60° it can be had in bloom early in January, and will continue flowering until May in any structure where the temperature does not fall below 45°. The plants should not be thrown away after the first flowers fade, for they quickly come into flower again, and are more beautiful than is the case at first. This year only have we discovered that they flower even a third time, and plants that did duty in January were again in full bloom through April and May, and had much larger trusses than the first or second time. Those who have not the temperature named may grow it successfully if they can give it a night temperature of 45° to 50° during the winter. Plants for decoration in 5 and 6-inch pots should be raised from cuttings annually. These are quickly produced if a few plants are pushed forward in brisk heat after flowering. The cuttings formed of young growths strike freely in sandy soil, either singly in small pots, or a number may be placed together, well watered, and then covered with a bellglass, handlight, or be placed in the propagating frame. If inserted together they must be potted singly directly they are rooted. As soon as they are established in 3-inch pots the points of the plants may be removed to induce them to branch. The plants are not pinched more than twice, and are placed in their largest pots as soon as a good number of roots has been made. When well established they may be grown in cold frames through the summer months, closing the frame early in the afternoon. By the middle of September the plants will be dwarf and sturdy, not more than 1 foot high, and should be given a light position in some structure where the temperature named can be maintained. These plants do well in a compost of fibry loam three parts, the other part being composed of leaf mould and manure, about one-seventh of the latter with the addition of a liberal quantity of sand.

**Toxicophlœa spectabilis.**—This deserves to be more generally grown for flowering at this season of the year than is the case. It is said to require cool stove treatment, but such is not the case, for it can be grown well in a warm greenhouse or where the temperature in winter does not fall below 40°. While making its growth it is benefited by a close moist atmosphere; such treatment as generally given to Azaleas will suit it admirably in this respect. It will do well in the conservatory where flowering plants are kept during the winter, for such structures are generally a little warmer than the greenhouse. When well grown it will make shoots each season about 18 inches in length, from which it produces terminal trusses of small white highly fragrant flowers, and smaller trusses from the axils of the leaves for a foot or more down the growth made. The plant is of upright growth, and it does not branch freely without due attention is paid to pinching the shoots of young plants. When the plant has attained a fair size the shoots can be tied out to form a bush, or it can be well cut back after flowering—that is, when it has attained a sufficiently large size. It is propagated by cuttings and layers when the wood is in a half-ripened state, but being of a woody nature striking cuttings is rather tedious, and it is better to purchase the plants required. It does well in a mixture of peat, loam, and sand, the two first in equal proportions.

**Rogiera gratissima.**—This beautiful and useful plant should be planted out in every warm greenhouse or conservatory, for it will produce in this position abundance of delicate pink flowers, which are very fragrant during the summer and winter. The flowers are very useful in a cut state either for vases or bouquets, and this plant yields its flowers over a period of several months, for when one crop is cut the plant breaks into fresh growth and flowers again. Cuttings of the young shoots strike freely in sandy soil if covered with a bellglass and plunged in gentle bottom heat and shaded from the sun until they are rooted. It flowers freely in a small state, but these should be removed as they appear, to induce the plant to make growth and become bushy. It should be grown in an intermediate temperature until it attains some size and strength, when it is better planted out, and yields more flowers than when kept under pot culture. Care must be taken while growing it on not to allow it to suffer by insufficient root room. A liberal supply of water is also needed while in active growth; in fact, the soil should never be allowed to become dry at its roots; a suitable compost being loam, peat, and leaf mould in equal proportions, with sand added.

**Rhynchospermum jasminoides.**—Although this old and useful plant grows well under greenhouse treatment, it nevertheless makes much greater progress when assisted by gentle heat to make its growth. Plants that have done flowering may be repotted if they need more root room; a small shift only should be given, and the pot used should be liberally drained. The soil, which may consist of peat and sand, or loam, sand, and about one-seventh of manure, if the latter a little charcoal may be added. While growing a liberal supply of water should be given both at the roots and over the foliage. Young plants in heat make growths many feet in length in a season, which is desirable if they are to be grown into a specimen size as quickly as possible; under cool treatment these growths are not so freely produced. A little shade is beneficial while the growth is being made, then full sunshine should be given to ripen and harden the wood, the plants rested in a cool house and carefully watered at their roots.

**Grevillea robusta.**—Any plants that have become too large for ordinary decoration in 5 and 6-inch pots should not be thrown out, but planted to afford greenery for cutting for associating with flowers. The Fern-like leaves of this plant are most serviceable for this purpose, as they last well in a cut state even after they have been packed and have travelled a long distance. A suitable place for them is against a wall at the back of the greenhouse, Peach houses, or amongst large plants in the conservatory. If possible they should be planted out in a cool structure, for the leaves are more lasting than when cut from a close moist house.

# THE BEE-KEEPER.

## NOTES ON BEES.

### QUEEN AND DRONE-RAISING.

Now that the season has come when bees will require attention, not only for the purpose of keeping up the strength of every hive, which is the best and only means to obtain heavy yields of honey, but for the purpose of using the proper means to have every stock in order for next season, two essentials towards that important point are absolutely necessary. Young, fertile, and prolific queens raised from the best strain of bees of any of the pure races—Syrian, Cyprian, and Ligurian—are improved by crossing, but the Carniolians with me do not seem to be improved by crossing. I cannot say they are impaired, but during the eight years I have had them now the pure ones have given every satisfaction. Next to the careful selection of queens come the drones, which must be selected from another strain or hive having all the good qualities bees should possess. The moment this hive is of sufficient strength some drone comb should be inserted in the centre of the hive, but to be removed after the drones are hatched, either to the extreme sides or better altogether, as excess of drone combs is unnecessary and is sometimes injurious. To insure success it will be better to remove queens and selected drones to a distance free from the influence of other drones. Where that cannot be carried out more hives should be chosen to raise drones, so that they will be numerous enough to insure the proper fertilisation, while at the same time the drones of hives not desired to wed with the selected queens should be kept under. Whenever the selected drones are hatched—which should be, if possible, eight or ten days before the queens—the hives containing them should be fed, so as to have them vigorous and much on the wing, and if it can be so managed to have these drones along with a young queen all the better. We have had two summer-like days, but two only, the 6th and 7th May. The former day the temperature rose to 65° and the bees carried well. The latter date the temperature rose to 70°, but the bees are not quite so active and look as if a change was near.

I was under the impression that all my hives were in possession of their full breeding space, but on the 6th of May I discovered one evidently in a state approaching to swarming. On examining it I discovered it was in only two square Stewarton boxes. The third one was given it, and the bees at once took possession, and comb-making commenced rapidly, filling its box with comb. Early in June most of my hives will be ready for supering. The Charlock will be in bloom, and if the weather be fine supers will be rapidly filled. Increased room will be given in supers only. The stock hives with their broody queens will cause the most of the surplus honey to be stored above. What is not will be amply sufficient to tide the bees over till the next summer, as the last year's honey has done in this, bringing the bees through one of the most untoward and protracted seasons on record to swarming point, and in a state to store surplus honey without so much as removing a single cover from one of them. What say our manipulators to that?

Should any of my stocks swarm through any unforeseen circumstances I will not thwart their inclinations, but will if possible join two together, transferring supers and perhaps part of combs to the swarm which shall occupy the site of old stock, and it shall get the task of raising one or more queens.

I have penned the above in anticipation of what is likely to happen, and the mode of management described is what I have previously found the best, trusting it will be found to be the same by your bee-keeping readers who follow on the same lines.

### STATE OF MY HIVES.

On the 19th of May we enjoyed a fine day, the first one for a fortnight past, the temperature rising from 32° to 60°. We have not had severe frosts yet, although the weather has been far from being genial. Vegetation has been almost at a standstill, and bees have had a hard time of it. Many have succumbed altogether: the keen winds penetrating to the interior of their hives prevented their progressing with breeding, and a dwindling away or a general exodus has been the result in fed hives.

That my own bees have had an entire immunity from the destructive effects of the cold I can scarcely think, but I cannot detect any serious diminution of their numbers, as is certainly the case with my neighbours over the hedge, who had to feed to keep them alive, which liveliness has brought about to appearance the death of at least a third of their number. My Carniolians have kept withindoor during every cold spell, and work with extra vigour whenever a warm day occurs, which have been few and far between. On the 20th ult. the temperature was down to 47° with rain. The alighting boards and boards of ventilating floors are covered with the sealings of drone cells. This is what every bee-keeper rejoices to see, indicating

as it does that swarming time is drawing near or that they are in readiness for supering; but the weather is suitable for neither, and the honey season is at a distance yet.

With large hives and healthy prolific young queens there is no danger of the queen being crowded out, but with the teeming population there is a danger of the stores becoming exhausted, resulting in brood-drawing and starvation. The former will take place, even although a scarcity inside is not imminent; but when a continued and protracted spell of cold weather continues at this season it is almost sure to occur.

To prevent such a calamity and losing all prospects of a honey harvest, feeding must be resorted to sufficiently to prevent disaster and disappointment to the bee-master. I have proved that it is a mistake to feed at a season when it is fatal to bee life outside the hive, but we hope that is past; but whether or not, the bees must be fed now if this dull weather continues. We frequently have to do so till the end of June, so do not withhold the syrup till then if required.

### A DAY'S OUTING.

In response to a request of Miss C. R. Macdonell of Glengarry (niece of the late Lieut.-Col. Macdonell, who held the gates of Hugoumont at Waterloo) I went to Rothesay, Island of Bute, on Saturday, the 15th of May. The temperature of the morning was 35°, with a strong north wind, and was a most unpleasant day for an invalid to attempt the manipulation of bees one way or another. Loch Gaoith means "Windy Loch," and certainly we experienced it in full force. To take the combs from some Renfrewshire Stewarton hives of nine years' standing and refit the frames with comb foundation before an audience was ostensibly the work that was to be done, as well as to overhaul some double-cased frame hives having their combs parallel to the entrance, which from the glowing description by the vendor should have been first-rate. I confess that I have an aptness to discover faults more readily than virtues, and in this case it was no exception to the rule, and as I consider the experience will be interesting and instructive to your readers will describe things exactly as I found them.

The first hive that arrested my attention was a Renfrewshire Stewarton arranged in detail as that gentleman has long taught. The only improvement I suggested was a ventilating floor and a slight alteration in the covering of hive proper, dried grass in sufficient quantity, but not overmuch—just what would give results similar to the nest of the wild bee, mouse, or the hedgehog, not to imitate a rag store or a rick of hay in a position to draw moisture, and be transformed into a muck heap in a short time. There was a departure with all the other hives from the orthodox style. The outside cases had the proverbial plinths and flat roofs, which were to be of so much importance, according to those who, perhaps, could make no other sort, at least to pay them so well as did these flowerpot carriers. Although the hives had about 15 inches of doorway, these outer cases had only about 3 inches wide by three-eighths high—one of the greatest mistakes that can well be. The flat roofs were covered with zinc, and to make it lie close was thoroughly nailed in perhaps a hundred different places, every nail hole being an aperture to take in water. These, with the plinths and the case resting upon the floor instead of projecting over it, must, from their appearance, have had the surroundings of the hives proper in a pitiable state with damp. Thanks to the single-cased covers and hives, the latter standing free from the case was not affected by the damp, and the result is, with all the drawbacks, these hives are crowded to the door with bees, and occupy two 9-inch Stewarton boxes, are ready for swarming or supering, and have neither been fed nor otherwise interfered with.

After getting through with the Stewarton hives I went to the frame hives, but these were in a very different state to that of the Stewarton ones, all being dead, or nearly so. The frames had the orthodox three-quarters of an inch bars, that gives the bees so much extra labour propolisising quilts, building combs above the top bar, and past the end ones, which makes manipulation so difficult, irritating the bees to the greatest extent, and killing many of them. In all the hives I ever possessed or made I never had or knew of a single comb being built between the hive wall and the frame.

But even worse than that, the frames were not all supplied with distance pegs, following the advice given by our contemporary to have the distance between the frames wider during one season than at another, so that instead of having one comb to every frame some of them had two, neither of which could have been of use to the bees had they survived. I advised the immediate burning of these hives, and to look well at the contrast between them and the Stewarton ones. The day was cold, and the hills carried a heavy mantle of snow, so I left for lower and more genial ground, glad to get away from the cold, the mismanaged, and worthless hives, but not before warning their owners how to act in the future, and to keep everything in its place, particularly that of slides and

frames to  $1\frac{1}{2}$  inch from centre to centre, and have no frames less in breadth than  $1\frac{1}{4}$  inch.

In the town I met with some old and intelligent bee-hands, who last year had taken much honey from their Stewartons, one to the extent of 200 lbs. from each hive of honeycomb, but from the "Combination hives" not more than 10 lbs. I may here mention that combination means nothing more than the name. I did not require to give advice in these instances, because the whole of these persons have discovered the mistake in attempting to keep bees with profit in these hives. At this place last year, while the bee-keepers were so successful with the Stewarton hive, a minister had a number of Combination hives, but got 4 lbs. only from each hive. One man exclaimed that "they minister bodies had been the direct cause of leading beginners astray, and into needless expense, by attempting to teach that they were unacquainted with, but who had been goaded on to this by those interested parties who had made them their tools." All this I did not endorse, and could not. There was much truth in the statement, but I am intimately acquainted with many clergymen who are very successful and clever bee-keepers, but these gentlemen are, as a rule, not so conspicuous in print on bee matters as we should wish to see.

On my way home I got information of a person who had fourteen Combination hives, and only one survives. So much mortality amongst bees located in hives of that construction cannot be wholly due to the hive. The management, or mismanagement, surely must be at great fault. Doubtless shallow hives, and their having their frames across the entrance, are not so suitable for bees as the Stewarton hive, and we have good proof of that when we see both sorts of hives managed alike and the Stewartons coming out strong at a date, while the others in the frame hives are dead. Still I know that even these defective hives could be better managed, so that there would be less per-centage of deaths than has been with them this season, but cannot advise their use. The tiering system is coming more and more to the front every day, and is generally adopted by intelligent bee-keepers; but I must protest against the name "new" being given to it, as is the case in the *British Bee-keepers' Record* for this month. However, the aggressor in this instance is, like many more bee-keepers of the present day, without experience, but they must be kept in check all the same.

"F. J. J. B." has had difficulties in wintering his bees in the Stewarton hive, losing three times as many bees from it as from the Pettigrew hive. Without having fuller particulars about the hive in question it is difficult to say the reason of so much loss of bees. Glass is doubtless a bad thing in hives, but all that is of it in the Stewarton hive should not seriously affect the bees when you have a ventilating floor to it.

The proper way to winter bees in the Stewarton hive may be summed up in the following:—Plenty of bees and stores, thoroughly protected from wet, and the tops of the hive well covered with dried grass, and better that the sides be also protected, so that the hive is kept at a uniform temperature. The bees should have an ample doorway, the slides on the top of the hive should be withdrawn. If these things are attended to no ill should befall any Stewarton hive during the most severe winter. If there is a paucity of bees the combs will get mouldy, as they draw damp from the atmosphere. If there is a scarcity of meat the bees will be restless and fly much, the same thing occurs if they are kept too close. We shall be glad to hear further particulars from you, as reports in cases of failure are of as great importance towards the furtherance of the science as are those of success.—A LANARKSHIRE BEE-KEEPER.

#### TRADE CATALOGUES RECEIVED.

Thames Bank Iron Company.—*Illustrated List of Boilers, Stoves, Heating Appliances, &c.*

## TO CORRESPONDENTS

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles in-

tended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**TO CORRESPONDENTS.**—We desire to assure those of our correspondents whose letters and communications are not promptly inserted that they are not the less appreciated on that account. Our pages are practically filled several days prior to publication, and letters arriving on Wednesday morning, except by special arrangement, are invariably too late for insertion. The delay in the publication of some of these is not of material importance, but reports of meetings and shows held a week previously lose much or all of their value if not received in time to appear in the current issue.

**Grubs in Strawberry Bed (W. G. B.).**—The specimens you sent last week are the larvæ of the large crane fly, *Tipula paludosa* or *gigantea*. They are very difficult to eradicate.

**Caterpillars on Vines (J. C.).**—The caterpillars sent appear to be the larvæ of the Poplar Lutestring moth (*Cymatophora* Oo), which is not abundant. It has been observed that some larvæ that feed on the Poplar and Willow will also feed on the Vine.

**Books (A Lover of the Journal).**—We doubt if there is any book that will exactly suit your friend. Write to Mr. Upcott Gill, 170, Strand, London, on the subject, who publishes two or three works that might possibly be useful.

**Canvas Protector (T. A.).**—Without at least a drawing we cannot form an opinion on the matter. Exhibit a sample at a good local horticultural show, or at the Royal Horticultural Society's Provincial Show, to be opened at Liverpool at the end of the month.

**Pelargoniums Unhealthy (S., Carlisle).**—The plants were no doubt affected with the "spot" before being removed from the frame, but the leaves have turned yellow mainly through the check the plants received by their sudden transference from a moist to a dry atmosphere. They have perhaps also been too dry at the roots. Give them some clear soot water.

**Vines (J. G.).**—You supply no information whatever to enable us to form an opinion as to the cause of the disease of the Vines, and we can only suggest that they received a sudden check by cold during the early stages of growth. Particulars as to soil, temperature, and treatment would have been of great service in the consideration of the case.

**Dendrobiums (R. P. O.).**—One of the most effective Dendrobiums for exhibition at this time of year is *D. thyrsiflorum*, which with *D. Devonianum* you already grow. To these may be added any or all of the following:—*D. Bensoniæ*, *D. chrysotoxum*, *D. chrysanthum*, *D. crystallinum*, *D. Deari*, *D. Falconeri*, *D. Jamesianum*, and *D. nobile*, which can be had in flower now, are free and last well.

**Peaches and Nectarines Falling (W. A.).**—The most likely cause of the young fruit dropping is immature wood, the buds not being properly developed and the flowers imperfectly fertilised. The trees appear to be planted much too close together, and consequently make growth that does not ripen. Keep the growths fairly thin, so as to admit light and air; and in autumn, when the leaves part freely from the trees, lift carefully, and lay the roots in fresh loam nearer the surface.

**Weevils on Roses (W. Williams).**—Your Rose is attacked with the voracious weevil *Otiobrychus sulcatus*, which appears to be too abundant this year. If you quietly spread a sheet or something of that kind at night and shake the pests off the Rose you will catch many of them. They feed at night. If you clean the tree you may perhaps prevent others ascending by affixing cotton wool round the stem and smearing it with tar; or perhaps, better still, with a mixture of resin and sweet oil, two-thirds of the former melted, and one-third of the latter, smearing it along the base of the wall also; it keeps moist, and the weevils will not travel over it.

**Wood Ashes—Chemical Manures (F. J.).**—We should certainly not advise any "poor man" nor rich one either, to give the price you name for the sample of ashes before us for manurial purposes. You had much better purchase a little muriate or sulphate of potash, whichever you can obtain the most readily, and use equal parts of that and bonemeal, adding a fourth part of sulphate of ammonia to the bulk, and you will have a mixture that will do good to most trees, crops, and plants that need assistance. We do not say it is the best that can be made for everything, and if given in excess, or when not required, it is wasted. As a rule the prepared manures, such as Beeson's, Clay's, Jensen's, and Standen's (which are mentioned alphabetically) are the most convenient for amateurs and undoubtedly good.

**King of the Pippins and Golden Winter Pearmain Apples (Pomo).**—The original and true King of the Pippins, which is exceedingly rare, is that described in the "Fruit Manual" under that name. The variety usually known in the markets and under the names of "King Pippin" and "King of the Pippins" is the old Golden Winter Pearmain, the name of which was changed by Kirke, a nurseryman at Brompton, to suit some trade purpose about the beginning of this century. The Seek-no-Further of Herefordshire is no doubt also the Golden Winter Pearmain—Hereford notwithstanding. The season of all keeping fruits is very variable, and depends as much on soil as climate. We have now blenheim Pippin quite sound and fresh from a clay soil, and Marie Louise Pear from the same soil keeps till January and February. The time of ripening of Golden Winter Pearmain is given in the "Fruit Manual" as October to January, and this we have found is correct.

**Strawberries—Vines (Old Subscriber).**—If early runners are established, and good plants with bold crowns produced by October, these seldom fail to throw up good trusses of flowers if not unduly forced and the varieties are suitable for pot culture. In the absence of any information respecting your plants we can only suggest that they did not form and mature strong crowns in the autumn. When "strong and vigorous" Vines produce little or no fruit it is because the growths were not well fed and ripened in the summer. When the roots descend into wet subsoil apparently robust growth often follows, but it is not fruitful growth, for the roots cannot find the requisite nutriment in inert soil. With roots working freely in good

soil near the surface, the growths trained thinly in the summer, the foliage kept clean, and the wood well ripened, Vines are bound to show bunches, and, rightly managed, perfect fruit in due time.

**Melons not Swelling (A. L.).**—There can be little doubt that you indicate the cause of the failure in the sentence "It is impossible to keep up the required heat at night, owing to bad arrangement of the boiler." Melons cannot be growing satisfactory in a temperature too low for their requirements. In defectively heated structures it is a mistake to raise and plant Melons so early in the season as you have done. By planting very strong plants at this season of the year in good soil over a bed of fermenting materials we have had good crops of excellent Melons in a house where no means of affording artificial heat were provided; but the house was closed early with much sun heat, and the glass was covered with a blind on cold nights. If you adopt the same plan of arresting radiation you will have a night temperature in your house from 5° to 10° higher than without any covering, and this may make all the difference between success and failure.

**Planting Vines (Ferndale).**—The Vines would probably have been better had the roots only been covered with about 4 or 6 inches of soil. If this had been done, and the border mulched in early spring to prevent evaporation, the roots could have been kept near the surface. They descend quickly enough without placing them too deeply in the border. Vines always make a certain amount of growth before the roots commence activity. When the roots commence working the foliage assumes a much darker and healthier shade of colour. The foliage, even of established Vines, is always pale at first until root-action has commenced. If the border has been in a proper state for moisture since the Vines were planted and the roots are still alive, they are certain to start working; the deeper they are laid in the border the longer generally are they before action commences. The formation of the roots near the surface is due to the extra warmth and moisture which they receive. We do not believe it prudent to bury much of the stems of Vines to induce the formation of roots from them, for they are generally formed at the expense of the lower or main roots. It is very difficult to say why your Muscats have not set well without knowing exactly the condition of the wood, the state of the roots, the temperature and moisture of the atmosphere of the house, as well as other cultural particulars to which they may have been subjected. The dull weather should not have been the cause if all other conditions were favourable. We have generally noticed that Muscats set the best when the weather is not too bright. Some excellent and successful cultivators apply light shade to the glass during very bright weather while the Vines are in bloom.

**Orchids (Idem).**—There can be no doubt that the compost in which your Orchids were potted was rendered sour through being kept too wet during the winter. Many species and varieties of Orchids require very little water during the winter or resting period, and if over-watered in that stage the roots are certain to decay. After potting them they should be watered with great care, being kept rather dry than wet until the formation of new roots and the commencement of growth, then more liberal supplies should be given. Sphagnum moss in a living state is largely used by most Orchid growers for many varieties, and they do wonderfully well in it, provided it is removed when it becomes decomposed and is replaced with fresh—that is, annually or every second or third year, according to the nature and requirements of the plants cultivated. Ants are very troublesome and difficult to eradicate. Strong petroleum and water poured into their nests will destroy them, so will boiling water in which a good quantity of salt has been dissolved. Another plan is to set traps, such as basins, small bottles, &c., with some sweet material in them, and then immerse them into boiling water daily. Hollow bones with a little fat left in them are also good traps for them, and by carrying out persistently these methods they can be got rid of. But this is a work of time and requires patience.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (W. B., Lancashire).—1, *Cereus Jamacaru*; 2, *Cereus speciosissimus*. (Wm.).—1, *Gloxinia tubiflora*; 2, *Melissa officinalis variegata*.

#### COVENT GARDEN MARKET.—JUNE 2ND.

TRADE steady, and with good supplies prices lower.

#### THE FUTURE OF FARMING.

WHEAT-GROWING will probably dwindle to very narrow limits upon many farms, especially where there are inferior crops again this year, yet we may well inquire if those who fail in the culture of Wheat are likely to do better with other crops. One of our tenants could only obtain 24s. a quarter for his Wheat, and the yield of grain from that crop would probably not exceed as many bushels an acre. Another had no difficulty in selling his Wheat at 38s., and the average yield of his fine crop was close upon 48 bushels an acre, which represents a return for grain alone of £9 18s., and if we add the value of the straw £2, we have the very satisfactory total of £11 18s. per acre. Bearing in mind the very general recent reduction of rent we cannot refrain from asking if after all the farmer is such an object of pity as he is generally supposed to be? We may doubtless be told that not many farms would afford so fine an average as the high one mentioned; yet if we ask why, shall we not find blame attached to the soil and not to its cultivation? Puzzled! it might be said truthfully enough of many a farmer who now sees his corn crops of a sickly yellow hue and weak in growth. He tries to account for it by talking of drought, or wet, or cold, but at the same time his mind is beset with doubts of the condition and of his treatment of it. Not at all uncommon is it to hear a certain field termed a "bad" field, just as though it were incapable of improvement. A farmer whose span of life is fast approaching its full limit of three-score years and ten said to us recently with an air of doubt and a tone of inquiry, "I have said I would use no more artificial manure, but I don't know?" Low prices for farm produce had evidently set him thinking, and raised doubts in his mind as to the soundness of his practice.

In the future of farming we shall, simply because we must, possess sufficient knowledge of the nature of the soil

and its requirements to impart as much certainty as possible to the work of its cultivation. Our work can never aim at the precision of mere mechanical effort because results must always be influenced by changes of weather, but it is possible by high cultivation to impart a much greater degree of certainty to it than has hitherto been achieved generally. Take for example two meadows, one drained carefully, and with equal care bestowed upon the regular and timely application of manure to it; the other undrained, and either unfertile or manured very late. In the first we have early growth and a hay crop of singularly uniform abundance; in the last, late growth and a hay crop so seriously affected by weather that a few weeks of dry weather in April and May proves fatal to it. The condition of the Wheat crop at the present time may be taken as another example. Field after field may be seen with plants of sickly hue and stunted growth, and such Wheat fields are largely in the majority; but there are others, or rather there are farms where the whole of the Wheat is in excellent condition, the plant is already nearly a foot in height, and its dark green hue is entirely satisfactory. Not simply is this high colour and free growth to be traced to the use of chemical manures alone. We know farms where sheep were folded upon Clover which was followed by Wheat that now is positively rampant in growth, affording additional proof of the importance of sheep-folding in farming. Upon one of our farms there is a twenty acre field of Wheat, part of which had dressings of home-mixed chemical manures, but the other part had no manure, the bailiff being strong in his assertion that it required none. He now probably regrets being so positive, for the plant on the unmanured part though fairly robust is poor in colour and weak in growth in comparison with the rich dark green and almost rampant growth of the other part. We do not much regret this, for the lesson is a valuable one, and we shall be able to ascertain exactly how great is the advantage of using the manures we have so often recommended.

Having regard to the important part which chemical manures must play in the future of farming, we may mention that in the opinion of some practical men we have been somewhat rash in so strongly recommending the same sorts and quantities of manures for the use of farmers generally. Well, it may be that we have been a little positive about a matter of such immense importance, but then have we not reason? The results achieved in Sussex and Aberdeenshire have been so remarkable that we dare risk something in our ardent desire to see similar results in other parts of the country. So confident are we of the general value of the manures, that we have used several hundreds of pounds worth this season for the crops upon our Suffolk farms, and, judging from the appearance of the crops now, we have reason to believe our expenditure was a wise one. How few farmers will try and ascertain for themselves what is best for the soil of their farm! Knowing this, and knowing too that potassium, phosphorus, and nitrogen are the chief elements of fertility with which it is necessary that all soils should be stored, we have ventured to recommend them generally, confident that though there might be some waste by the use of more of one or other sort of manure than was necessary for certain soils, yet the general result must be so good as to prove highly beneficial. Earnestly do we wish it known that we write open to correction, for certainly we can claim that the end and aim of our teaching is the improvement of farming, the good of farmers, and if any of our readers can help in so good a cause, most cordially do we invite their co-operation.

(To be continued.)

#### WORK ON THE HOME FARM.

The first sowings of White Mustard have come up well, and if the weather continues showery some nitrate of soda will be sown broadcast over this catch crop, our object being to induce strong growth for ploughing in as soon as the seed pods are fully developed. The land now under this treatment was both poor and foul last year; we have got it clean, and hope now to so store it with fertility that it will yield really full crops

next year. Swede-sowing both on the ridge and flat has been done under favourable conditions; the Mangolds are growing freely, so that on the whole we have reason to hope for a good root crop and an ample store of food for next year. The frequent showers that have fallen since our last note was written have done much good to the hay crop; all the grass is growing freely, and we may now safely conclude that the crop will be abundant. Nettles, Thistles, and Docks have also shot up on grazing pasture, but we have not yet been able to cut them down, as all available labour has been given to keeping under weeds among spring corn. Showery weather renders this an arduous undertaking; our difficulties have been increased by careless work of the labourers, who, having taken the work to do by the acre, appear to care for little besides getting over the ground as fast as possible. It is of course the bailiff's duty to see that such piecework is well done, but we find it necessary to give frequent attention to it in order that our wishes may really be carried out. Charlock, Thistles, and Couch Grass are our most troublesome weeds, which it is no easy matter to keep within reasonable bounds, for when once these pests become established in the soil they cling to it with a persistence that is most disheartening. There is, however, nothing for it but equal persistence on our part in our efforts to eradicate them, for we cannot hope for really full crops while the land is foul with weeds. Sheep-washing and shearing must now have attention, and especial care be taken to put quiet careful men at the work. About a fortnight is required after the washing before the wool is in condition for shearing, the sheep being kept upon grass or green crops where the wool cannot become dirty again. Some few scars are always found upon sheep that are restive under the shearing, and time must be allowed for them to heal before the dipping in Cooper's mixture is done. We like this summer dipping to be done as early as possible in July, as it then serves to keep off attacks of flies, which so frequently prove troublesome to the sheep. We consider negligence in such matters highly reprehensible, leading, as it does, to much suffering among the sheep.

#### OUR LETTER BOX.

**Grass Manure (W. T. H.).**—Professor Jamieson's formula for Grass has been published more than once in this Journal, and is repeated as follows:— $\frac{1}{2}$  cwt. nitrate of potash,  $\frac{3}{4}$  nitrate of soda,  $\frac{1}{2}$  cwt. superphosphate of lime,  $\frac{1}{2}$  cwt. steamed bone flour. This is for an acre, and should be applied in February. Some excellent and successful agriculturists consider muriate of potash answers as well as the nitrate and it is much cheaper, and we know of an instance where sulphate of potash (kainit), which is cheaper still, has proved very satisfactory. Particular manures have not precisely the same effect in all soils, and on cold wet land  $\frac{1}{2}$  cwt. of sulphate of ammonia has been found more effectual than  $\frac{3}{4}$  cwt. of nitrate of soda. With the judicious use of concentrated manures of the nature indicated, and the prevention of weeds, the yield of both Grass, grain, and root crops might be easily doubled in many districts in this country; and we are convinced that farming in the future cannot be profitably conducted without a liberal yet intelligent use of what are commonly described as artificial manures, but which are nevertheless very real in their effects. We are glad you consider our farm articles generally instructive, and are obliged by your suggestion.

**Condensed Milk (Inquirer).**—The following extract from Professor Sheldon's great work on Dairy Farming may help you:—"There are various methods and recipes for condensing and preserving milk, among which the following may be mentioned. 1, Add sugar, evaporate to one-fourth, solder in cans. 2, Add carbonate of soda and white sugar, evaporate to dryness, cut into cakes. 3, Add sugar and alkali, evaporate to dryness, crush, powder, and bottle. 4, Evaporate to one-half, beat up white of egg, simmer, skim, strain, and boil. 5, Carbonate of soda one-half drachm, water one fluid ounce, dissolve, add milk one quart, sugar one pound, reduce to syrup in a steam bath, and finish the evaporation on plates in an oven."

#### REMARKS.

23rd.—Distant thunderstorm early, with heavy rain; dull and damp, except from 5 to 7 P.M.  
 24th.—Fair till 10 A.M.; then almost continuous rain day and night.  
 25th.—Fine, with some sunshine.  
 26th.—Fine, with a good deal of sunshine.  
 27th.—Heavy rain early; dull first part of morning; fine and bright after; gale in afternoon and night.  
 28th.—Fine and bright, but with a short sharp shower about noon.  
 29th.—Fine early; occasional showers in morning; lovely afternoon and evening.  
 A week with a good deal of bright and pleasant weather, though there was only one rainless day, and the total rainfall is large. Temperature about one degree below that of the preceding week, and nearly three degrees below the average.—G. J. SYMONS.

## WEEDS AND WASTE.

**W**EEDS are exhausters of the soil robbers. They rob the land of its virtues, steal the food of useful crops, destroy the credit of cultivators, and empty the pockets of the owners of land. Weeds have done more injury to British husbandmen than all the importations of foreign grain has, for if there had been none of these robbers the increase of home grown food would have been enormous, with no more cost for seed, manure, or rent, and only a little more for labour if timely applied. The condition is important to gardeners and farmers alike, for "timely action" is undoubtedly the great lever of economy in cleansing the land and conserving its virtues for profitable or desirable crops.

That familiar implement, the hoe, is a great factor in successful culture, and its prompt and frequent use is a certain incentive to the growth of plants. It is the great annihilator of weeds which, if allowed to develop, gorge on the virtues of the land and leave it the poorer. It were as hopeless to expect weed-infested ground to maintain its supporting power as to rely on a full crop of hay from fields constantly grazed with cattle or sheep. The only difference is that the animals deprive the land of its resources above, the weeds extracting them from below the surface. The effects are the same, only the former evil is more apparent, though the latter is not less real.

Of what avails draining, digging, trenching, ploughing, and manuring if whatever may be intended to cultivate does not derive the benefit of these operations? They are quite costly enough when the accruing advantages are immediately directed to the object desired; but when weeds are allowed to have a great share of the proceeds, just to that extent is the money expended in preparing and enriching the soil wasted. Weeds and waste go together in the management of land under cultivation, and no excuse that can be urged in extenuation, and no argument that may be advanced, can alter that fact. Everything that grows needs food, and the very existence of growth is visible evidence of the appropriation of the virtues of the soil—of food being extracted from it. When this is represented in useful crops or plants that it is sought to perfect, in those the cultivator has his reward; if represented in weeds, in those he incurs the penalty of neglect, waste and loss. There is no mistake about this. The loss in some individual cases may be small and comparatively inappreciable, but in others it may be both seen and felt, while in the aggregate it is enormous.

Judging by the complacent way in which weeds are tolerated among garden and farm crops it might be supposed that they live on a different kind of food, one crop not depriving the other of the means of support. It should be known that they live on exactly the same kind of food, though the relative proportions of the ingredients may vary, as in the case of cultivated plants. Weeds and the crops they accompany abstract the same food from the common store. They are competitors, each leaving something less

for the other; and weeds, if permitted to develop, will certainly have their share.

As an illustration of the competing power of weeds and cultivated plants we may adduce two familiar examples—namely, one of the commonest of all crops, Wheat, and one of the most ubiquitous of weeds, Groundsel. What do we find? This: Leaving out what may be termed minor ingredients in both cases, we find the prominent constituents of both as ascertained by analyses are phosphoric acid, lime, potash, and magnesia. Of these, taking the mean analyses of grain and straw, Wheat contains of phosphoric acid 18.3, lime 4.65, potash 18.3, magnesia 7.92. Now to Groundsel. This contains of phosphoric acid 7.65, lime 16.11, potash 29.85, magnesia 6.29. It will be seen that both partake of the same ingredients though in differing proportions, yet both are equally exhausting. Groundsel is a potash plant; so is the Potato, and when both are grown together, as is often the case, the useful crop is deprived of a large amount of the chief agent in its development. Potash is thus essential for Potatoes and Groundsel, and when it is applied to land for those crops both are benefited. These instances show that the food of useless weeds and useful crops are similar, therefore weeds very decidedly represent waste. It is a marvel that they are permitted to flourish as they do among cultivated crops in gardens and fields.

Some time ago I wrote to a farmer who grows the best crops of Potatoes, followed by the best crops of Wheat, of any that come under my observation (which is not very limited), on a matter not foreign to the subject of these notes. He grows side by side—that is, in breadths in the same field—early Potatoes, such as Beauty of Hebron, which produces short tops that die down in July; Regents, that grow say six weeks longer and about three times stronger; Magnum Bonums, that grow very much stronger still, and do not ripen till very late in the autumn. Probably the majority of persons would imagine that the strong and late-growing varieties would exhaust the land much more than the dwarf earlies, and consequently there would be a marked difference in the Wheat crop in the respective plots. This was the view of a few gardeners to whom I spoke on the subject, but as I inclined to a different view information was sought to settle the point. The following is the answer obligingly sent, the writer of it not knowing the object of the inquiry:—

"In reply to your query about the effect of different kinds of Potatoes on the following corn crop, I think there is very little difference. I have often looked for one but could never find anything striking, and I think if I lean to an opinion either way it is in favour of the stronger-growing kinds, and I fancy the reason is that their tops have smothered the weeds and rubbish more effectually. There is an impression abroad that if a crop is a failure (such as a thin crop of Wheat owing to loss of plant from wireworm) there is more nutriment left in the land for the next crop. This is a great fallacy. I believe a full heavy crop of anything will exhaust the soil no more than a bad crop of the same description."

That is a very significant letter. When a crop is thin it is not considered to be worth cleaning. The weeds have then a merry time growing, flowering, seeding, and exhausting the land. This they do just as much as a "full and heavy" food crop would. The weeds eat out the virtues of the soil and give nothing in return. Millions of pounds worth of labour and manure have been wasted on weeds in this country during the last fifteen years.

What is the remedy? The hoe or other scarifying implement timely applied—that is, not after the weeds grow, but before. Ten thousand can be prevented with a ten times less expenditure for time and labour than as many hundreds can be destroyed after they have been allowed to get firmly established, while in the former case the fertility of the soil has been conserved, and in the latter dissipated.

A man can run a hoe through an acre of ground with less

exertion to himself, and with far greater advantage to the land, when there is only the faintest tinge of green by upspringing weeds, than he can cleanse one-tenth that extent after they have approached or attained to a flowering size. Assuming the man has 3s. a day, the saving effected by prompt action is obvious and important. But some wage-payers, for garden labour especially, conceive that their money is being wasted when they see a man hoeing where there are not strong weeds. Such persons are not practical. They have not, in fact, "thought the matter out," hence really do not know what is good for themselves. Sound gardeners, however, know it, and some of them, perhaps many, do much good by stealth in rushing the hoes through the ground in the absence of the lord and master; and others would only be too glad to ply the hoe sooner than they do if they were not overwhelmed by other pressing work in spring. Driven by circumstances, not a few owners of gardens feel compelled to reduce as much as possible the labour supply. It is very easy to reduce too much and lose in the end far more than is gained in the beginning. Saving labour results in weed-infested land, and this means a greater waste of money than it is possible to compute. It is the farmers of such filthy land who first fail. They allow it to be overrun by an army of robbers, and trust to the impossibility of their not pillaging. Those market gardeners who enrich their land the most freely and prevent the growth of weeds the most sedulously, pay the highest rents and make the most money. They cannot afford to let weeds grow. They would be ruined if they did; and no labour is so productive to them as that by which weeds are prevented and the whole resources of the soil directed to the more remunerative crops.

Hoeing before weeds are visible is the most economical and effectual of all methods of procedure; for, besides preventing robbers feasting on the food in the soil, it admits air and warmth in spring, greatly accelerating growth; and in summer conserves the moisture that is continually escaping in hot dry weather through the fissures that form in soil when the surface is not periodically broken. By the practice indicated weeds are completely extirpated, and waste of the earth's resources reduced to a minimum. — EXPERIENTIA DOCT.

### ASPARAGUS.

I READ with interest the articles in the Journal recently upon the cultivation of Asparagus. There is one mode of assisting growth not referred to, and yet which, in my opinion, is such an excellent one that I think it deserves mention.

In the autumn after the growth is thoroughly ripened and cut down, give a heavy dressing of Sea Wraick quite fresh from the shore, cover it over with a thin layer of soil dug from the alleys to prevent all evaporation, and leave it to rot. In spring the birds will attack the beds in swarms, devouring a sort of maggot which then develops in the decayed Sea Wraick. When they do this it shows that the beds are ready for dressing. Remove the surface soil that was laid over the Wraick, gently point the beds over not more than 2 or 3 inches deep, then rake off the thick coarse undecayed stems of the Wraick. All the rest will be found to be almost entirely melted and ready to be washed into the soil when the next showers of rain come; and as soon as they do come there will be no mistaking the effect produced, as the melting mass of saline matter is gradually washed down to the roots of the Asparagus just as it is pushing its way to the surface. Talk of French Asparagus—none of it is to be compared to what I used to grow by this method. Another advantage is that you are not troubled with weeds.

One more observation even at the risk of being thought tedious. I have often heard it said that old Asparagus roots would not make good new beds. My experience is quite the contrary of this. I made some beds with two-year-old plants in 1865, I had to change my residence eighteen years afterwards (in 1883). The Asparagus was so fine that I could not make up my mind to leave it behind, so I had a lot of dug up (great big old stools) and, without any other packing, put in a railway truck and replanted in new quarters. The first year after removal I did not allow it to be cut, but since then it has been perfectly vigorous, and cut regularly with most satisfactory results.

I have generally heard people say that there is only one strain of Asparagus, and that any difference in quality is only the result of

cultivation; but that I refer to came from Cornwall, and from the first day I saw it to the present time I am convinced it is different from any other Asparagus I have ever seen.—A. D., *Isle of Man*.

IN reply to "Thinker's" inquiry (page 442), five years ago I made a trial on our Asparagus beds. We have six long beds. On two of these all shoots were kept cut until the middle of June. On the next two the thin spray was left from the commencement of cutting. On the other two spray was kept cut close from the commencement also; but strong shoots were left here and there singled until one was left at each crown. The following year the beds were anxiously watched, but I could not perceive any difference whatever on any of the beds; neither have I done so since. I have wished since that I had carried the experiment on the following year; but since then I have cut all away until the middle of June. Our Peas generally govern the Asparagus. As soon as they are in we leave off cutting the Asparagus altogether. I have given the beds a good dressing of manure every March. We first throw the soil into the alleys (or I should say part of it, as we do not bare the crowns); we then put on the manure and cover from the alleys. In April it has a dressing of salt. I should like to give another dressing when I leave off cutting, but I am not allowed to do so.—J. L. B.

### FRUIT STONING.

FEW things are so tantalising in horticultural practice as to have an abundant show of fruit blossom, and then have to experience a blighting of anticipations by the embryo fruit falling with or soon after the faded petals. Then the tiding safely over a good set raises anxieties as to the fruit swelling. Much does not swell—it "stands still," and is not long ere it falls. After this our care is about the stoning. The fruit may be cast in this, and our hopes of a crop for that year at least are lost.

There are two very important periods in the growth of fruit from the time the blossoms expand until perfection. There is the blossoming, during which the fruit is set or not set, depending upon the development of the organs of fructification, and the other is in the development and maturation of the fruit. The blossoming is a natural sequence of the formation of fruit buds in the previous season of growth. The buds are perfect or imperfect in the year of their formation. They do not change in the bud state. What they are formed when the leaves are on the trees, and what they attain in respect of perfection or imperfection, is effected whilst the foliage is upon the trees, and by or before it becomes mature and falls. Perfectly developed buds are, I am aware, formed at a very early stage. In some instances, as in the case of Vines, it is evidenced in bunches formed on laterals, and we sometimes have Peaches blossoming and setting in late summer when the leaves are upon the trees, and we have very frequent examples in Pears and Apples bearing secondary crops of fruit, but I have never known an instance of trees with no blossom buds when the foliage fell forming them during the winter months or season of rest. Peach trees that are forced early sometimes lose part of their leaves from red spider, and these plump the buds on the leafless parts quite as well as those that are furnished with leaves, and set and stone quite as surely as fruit on wood the buds of which had foliage up to a late period. Royal George and all the small-flowered Peaches and Nectarines bear more hardship in the loss of foliage than the large-flowered varieties, of which Noblesse, Grosse Mignonne, Early York, &c., are types. The first ripen or perfect the blossom buds, but the large-flowered seldom or never, forming imperfect pistils—that is, having short styles, and the anthers are devoid of pollen, if indeed the buds are not cast when we anticipate their swelling. I mention this because I have a recollection that "Thinker" asked my opinion upon this point—viz., "Did not the wood ripen after the leaves were off and in subsequent seasons?" I have no doubt of the wood hardening, but of its ripening I have very grave doubts, for ripening—that is, solidification during growth or with foliage, and hardening without foliage, are very different. In one we have a perfectly elaborated and assimilated formation of wood, and such a deposition of what physiologists term cambium, that a perfect bud is insured, certain to develop under favourable conditions in a perfect blossom, and to set and stone perfectly; but in the sappy growth we get crude sap and sound matter intermingled, the growth is not solidified as grown, the buds are not perfectly formed, the wood only ripens sufficiently to withstand ordinary temperatures of cold, and though we get a sheet of bloom there is no solidity of the organs of fructification even if we grant them to be perfect, and the blossom does not set or the fruit does not swell or stone. This in consequence of there being little or no ripened wood. "What!" I hear "Thinker" say, "No ripe wood! Why, you contradict yourself! There are Grapes borne perfect in every way on laterals, second crops

of Pears" Granted, but what a difference! It is the short-jointed thoroughly solidified growth that gives the Grapes on the laterals, stubby hardened wood that gives the second crop or fruit on the current year's growth of Pears. Soft, gross, long-jointed wood is no use for a crop in the current; it rarely is of any value for a crop of fruit in the year following formation, and it seldom if ever becomes so ripened as to lay the foundation of a healthy and long-lived fruitful tree.

The cause of fruit not stoning is due to similar conditions being wanted as regards the setting, and this entirely results from the conditions under which the growth is made, the buds formed, and the wood perfected in the previous season. What is wanted is thoroughly solidified growth, and foliage kept healthy until it falls naturally. This effected, we can hardly fail of perfect blossom, a good set, and a satisfactory stoning. If, on the other hand, we seek gross long-jointed wood the result is sterility. If we get blossom it is sparse; it may even set, but the chances are it will not pass the stoning process. This is very annoying, and though immature wood is a chief cause of fruit not stoning it is not by any means everything. We see trees year after year masses of bloom, and yet the appetite of the owner is not further gladdened. "Your ripened wood theory is of no use in bringing a crop of fruit," some may say; "my Cherry, Pear, and other fruit trees blossom well, they never give any fruit worth naming." I fully know your case, and sympathise with you. It hardly, however, comes within my present intentions, and yet without a set there can be no stoning, and we cannot well take account of one without the other.

Fruitfulness is a natural effect of a constitutionally healthy plant properly nourished. The weakly trees as a rule make the greatest effort at reproduction; the gross, but it by no means follows healthy, trees give the finest specimens of their kind, with an inherent tendency in the progeny to transmit the sparseness of reproduction, whilst the very gross are sterile. We clearly do not want the weak nor yet the gross, but we do require a plant to be so weak as to be fruitful, and so gross as to secure to us as large an amount of useful produce as possible. Growths that formerly would have been considered too gross and sappy and would have been cut away as useless are now fruited; shoots of Peaches as thick as the finger and twice the length of walking sticks are made to give fruit of a quality excelling any produced from wood that was only left a few inches long. In the one we have no more wood than is wanted, and in the other wood encouraged only for the purpose of cutting it away. The first is grown thinly so that light and air have free access, the other is grown thick and cut back to ripe wood at the base. Neither is of any good unless the wood is ripe. This is the first great principle in fruit cultivation. Without ripe wood there is nothing. We may get strong wood, large blossoms on Peach trees, large loose bunches of Grapes, even set them, but we may be certain that the Peaches will not stone and the Grapes will exhibit a large per centage of stoneless berries. On the other hand over-ripe wood has no such tendency. By over-ripe wood is meant the tendency to produce blossoms, as is common with early-forced Peaches, Cherries, &c., when the trees should be going to rest, which is fatal to the succeeding crop. The wood is never too ripe for a perfect blossom, and never too ripe for stoning. We must, however, have perfect blossoms perfectly fertilised or the fruit will not set; therefore what is essential to a good set is essential to stoning. In this respect they are inseparable, but they are divisible in that the wood may be only so ripe as to secure a good set, and yet so unripe as not to secure stoning. The most common instances of this are in the case of the Peach and Cherry, and in that of the seeding of Figs. Grossness, long-jointedness, and immaturity never fail of sterility; firm short-jointed wood properly nourished and matured cannot be had without attending increase.

Fruit does not stone, therefore, because the wood is not ripe, but the result may be equally disastrous through a weakening of the vital forces by overcropping, and accelerated by poverty. Just as in over-blossoming much can be effected by timely thinning the blossoms in strengthening those that remain so as to secure a good set, so in thinning the fruit and in affording nutriment much can be obtained in respect of the fruit stoning satisfactorily. The chief cause of fruit not stoning is not so much shown in the year of prevalence as in the preceding. It is due mainly to over luxuriance, a strong long-jointed late growth, the wood not solidified as made, and never thoroughly ripened. To check this root-pruning is the only effectual remedy. Training the shoots thinly so as to let in light and air, and summer pruning in that it exercises some check on root-action, is useful. Too rich soil is also bad, and worse is a deep border with the roots far from the surface. The only safety for fruit stoning is a short-jointed growth well exposed to light and air. To effect

this the soil must be firm, and the roots must be near the surface in a well drained border. No remedy need be tried but this—viz., lifting and replanting. Sometimes, however, the luxuriance is not great yet to make so much difference in the growth and its ripening as to affect the crop prejudicially at stoning. I have had Peach trees that have made over 6 feet of growth in a season, and ripened up to the ends, fruiting satisfactorily in a house, ripening the fruit at the close of May or June, whilst others in a house not ripening before August or September, lost a large per centage of the fruit in stoning. By training the growths thinner, and taking a trench out one-third the distance from the stem that the trees cover of the trellis, and as deep as the roots when the growth had ceased, or in late September, the supply of nutriment were so arrested that the growth ripened perfectly, and the fruit afterwards stoned satisfactorily. There was very little difference in the trees, and yet there was a great diversity in the result. Evidently the early trees had a longer season and more heat to mature in, the others had to mature their growth in the less favoured conditions of late summer, and consequently required greater space or more light and air, and a lessened supply of nutriment.

It is very similar with Vines. If we have large bunches we must have strong wood, and this must have more light and air, or a greater space for the full exposure of the foliage to all the influences of light, and not only this, but the roots must be kept near the surface in soil that will cause them to ramify and afford food in a steady progressive manner. Deep rich borders would only give long-jointed wood and loose bunches of stoneless berries, except of the coarser and freer setting varieties, which though they set well rarely finish satisfactorily. Some Grapes are notoriously bad setters and these it is generally considered require a higher temperature at the flowering stage than the free setters. Muscat of Alexandria, Black Morocco, and some others are given 5° to 10° more than other late varieties. Is it because they are more heat-requiring, or is it a consequence of the wood not being perfectly ripe? We know that sometimes these and some other Grapes do not set well even with artificial impregnation and a high temperature, and there are many more stoneless berries one season than another, and this we attribute to many things—a deficiency of water, loss of foliage from red spider, or scorching; in fact, we have causes without end; but the chief cause is no doubt immature wood, imperfectly developed buds or bunches in embryo. In the case of Figs we have excellent results from trees in pots and from those in borders of limited area with the growth near the glass in full glare of day, but we have gross wood immature and unfruitful when the borders are wide and rich, and the fruit is cast like Medlars after frost. We have, in fact, no Figs simply because the growth is not solidified as made, and the wood does not ripen, but remains soft and pithy.—G. ABBEY.

(To be continued.)

#### EUPATORIUMS.

I QUITE agree with your correspondent "G. P." at page 378 about the usefulness of the Eupatoriums there mentioned, and can testify that his management for plants in 48's or 32-sized pots is quite correct. *E. riparium* I find does best from cuttings, and to procure large specimens of *E. odoratum* I place out the plants after being cut back in rich soil in a moist corner 3 feet apart each way. These are kept well watered through the summer months, occasionally with liquid manure. The plants are stopped to keep them in shape until the middle of August. About the middle of September the roots are cut round with a sharp spade, leaving a ball about the size of the pot intended for their reception. The plants are taken up a fortnight later and potted firmly, left outside as long as weather permits, and drenched with water. The plants are then placed in a cool house, giving them plenty of room. Treated in this way they become 3 feet in height and as much in diameter. The only staking or tying required is simply looping up the loose branches. I do not agree with "G. P." as to the flat training. I consider naturally grown plants far more useful, especially for cutting. I have had plants of *E. odoratum* so treated with 150 heads of flowers open by the middle of November, and continued flowering till after Christmas. When the flowering season is over the plants are cut back and placed in a cold pit till the following May, then if too large divided with a sharp knife.—J. P.

#### CHRYSANTHEMUMS AND THEIR CULTURE.

(Continued from page 439.)

##### PLACING PLANTS OUT OF DOORS.

CULTIVATORS of Chrysanthemums must be guided in placing the plants out of doors by the locality in which they are situated; as for instance, those who reside on a hill are not subject to late spring frosts to the same extent as others in low districts. In the south of England the plants may safely be removed outside the

first week in May in a hilly district. A week later will be soon enough for the valley situations; and in the northern counties towards the end of the same month will be as soon as can be considered safe. It often happens that frame room at this period of the year is not very plentiful, therefore the Chrysanthemums are hurried outside rather earlier than is advantageous to them. It is wise to place them in such a position that protection from frost can easily be afforded by using light tiffany or other suitable material. A position at the foot of a south wall considerably reduces the necessity for protection. Large numbers of plants have been crippled through neglect at this stage of their growth by the want of light protection. When the points of the shoots are frozen a serious check is given to the plants, from which it takes them a long time to recover. Strong east and south-westerly winds often seriously injure them, large numbers of leaves being broken by such gales as frequently occur at that time of the year, as the leaves at that stage are so succulent they snap off readily, therefore every means should be taken to reduce the chances of this to a minimum. Stand the plants on ashes or boards to prevent the ingress of worms, allowing sufficient space between the plants that they do not become drawn up weakly.

#### BEST POSITION FOR PLANTS.

Before placing the plants in the pots in which they are to bloom the position they are to occupy during the summer should be selected and provision made for their reception, so that when potted they can at once be removed to their summer quarters. In this selection cultivators must be guided by the convenience at their disposal. A situation open to the full rays of the sun and protected from east and south-westerly wind should, if possible, be secured. Placing single row of plants on the side of a path running east and west in the kitchen garden, or one row on each side of a broad path running north and south, answers admirably, as where such positions can be afforded the plants can be easily attended to in watering and regulating their growth during the summer. If such a position as the one described is to be used it is better to stand the pots just within the border or quarter clear of the path, as the continual watering with liquid manure is apt to disfigure the gravel. Some growers plunge the pots, but except in the case of plants grown as specimens or bush plants for decorative purposes, where good foliage is especially desirable, I do not approve of the system, for the reason that in continuous wet weather, which often occurs towards the end of September, it is difficult to know when they require water. Excess of moisture at the roots is quite as bad as too little. Some people think Chrysanthemums cannot have too much water, but that is a mistake. I have seen plants denuded of a large portion of their lower leaves through supplying too much water to the roots. This is much more likely to occur in heavy retentive soils than in that of a sandy porous nature. If the pots on the sunny side could have a protection from the rays of the sun in continuous spells of dry weather by boards placed in front of the pots, I think this would be a considerable advantage both to the plants in keeping the roots cool and a saving of labour in the application of water as often as is required when the sun shines so powerfully. It is better to stand the pots on boards, slates, or tiles when in their summer quarters than upon a bed of ashes, as the roots penetrate through the bottom of the pot into the ashes for some distance in quest of moisture. When the plants are removed inside these roots are destroyed, which causes a considerable check to the plants. Worms, too, are not liable to penetrate into the pots, as they are when the pots are standing upon ashes.

Provision must be made for securing the plants from winds. This is best done by erecting a trelliswork to which the plants can be fastened. There are various means of effecting this. In some districts cultivators have at command an unlimited number of stakes of various lengths and thickness. A framework composed of these can be put up which is strong, cheap, and as easily taken down and stored during the winter. The stakes will last two or three years. The upright stakes should be of sufficient stoutness to prevent the plants swaying about, and placed at such a distance as their strength and the length of the cross rails necessitate. For the tallest plants three cross rails are necessary, while for the moderately tall-growing varieties two are enough, and one for the shortest plants. Some growers stretch stout twine from post to post instead of the rails, but this soon becomes slack by exposure to the weather, and is not sufficiently firm to prevent the plants rocking to and fro. The strongest and neatest method is that of making a permanent structure of iron standards. The end standards should be  $1\frac{3}{4}$  inch square, and be kept in position with iron supports 1 inch square. The intermediate posts may be flat iron  $1\frac{1}{4}$  inch wide and three-eighths thick. To these connect stout galvanised wire as the annexed engraving represents, to which a coat of paint has been given to

prevent damage to the tender shoots which sometimes occurs through contact with the acids used in galvanising the wire. Such contrivances are sometimes objectionable as a permanency; if so, they can easily be taken down and stored away if the wires are fastened by bolts and nuts. When the plants are potted finally a stake of the height which the plants will grow should be placed to each; some growers use one-quarter-inch iron rods made securely in the soil by means of three feet triangular in form. These have a neat appearance, but I think they are cold and not so good as those made of wood.

When the plants are placed in position these stakes are tied to the cross rails, which make all secure. The branches produced at the first break are spread out, and two of them are tied to other small stakes which are fastened perpendicularly to the cross rails as shown on fig. 86 to the required height, and when the plants are housed the two side branches are tied loosely to the centre stake. By spreading the branches out in the manner indicated better development of wood and foliage is secured by additional light and

Fig. 86.—Arranging Plants.

air; by placing the pots 1 foot 6 inches apart ample space is allowed between them. If the plants are arranged all together the rows should run east and west, and be at such a distance apart that the shade caused by one row of plants does not fall upon the row behind; to effect this a distance of 5 feet between the rows should be allowed. If the space at command is of the size to require several rows running parallel to each other the tallest plants must be arranged at the back with the dwarfier in front. Arranged thus all varieties can be accommodated to the best advantage. A knowledge of the relative height of each variety is necessary to effect this object, and for the guidance of the inexperienced I append a list of names with the height in feet. For the reader's observance of the growth and the better manipulation of each variety which has something peculiar to itself, it is a good plan to arrange all plants of each sort together; note of each can be more easily made than when the plants are scattered. To a close observer this is not the least interesting phase in the growth of Chrysanthemums. The height differs somewhat according to the treatment they receive. The excessively tall growth made by some varieties goes a long way towards condemning the method practised for the production of large blooms by some growers. If equally good flowers could be produced under any other system of culture it would indeed be a boon in many ways, but my experience prompts me to say that it is not possible, Nature must have a share of its own way. The heights which I give are based upon my own experience and produced by the methods of culture I am describing.

#### LIST OF VARIETIES WITH THEIR HEIGHTS.

THREE FEET HIGH.—L'Adorable, Val d'Andorre, Fleur Parfaite, Dolores, Mr. Cullingford, Miss Margaret.

FOUR FEET HIGH.—Golden Eagle, Golden John Salter, Hero of Stoke

Newington, Lady Hardinge, Lady Slade, Le Grand, Princess Teck, Princess Beatrice, Barbara, Fleur de Marie, George Sand, Yellow Perfection, Emperor of China, Chevalier Domage, Triomphe du Nord, Albert, Simon Delaux, Sœur Dorothee Souille, Golden Dragon, M. Henri Jacotot, Criterion, Meg Merrilies, Grandidorum, Bronze Dragon, M. Desbreaux, M. Moussillac, Madame de Sevin, Duchess of Edinburgh, Madame Deveille, Cullingfordi, Madame Goderaux, Princess Louise, Prince of Anemones, Angelina, Lady Talfourd, Miss Hope, Beauté des Jardins, Garnet, Père Delaux.

**FIVE FEET HIGH.**—Hiver Fleuri, Flamme de Punch, Dr. Macary, M. Astorg, Margot, Fabian de Mediana, Marguerite Villageoise, Souvenir de L'Ardene, Mdle. Lacroix, Cloth of Gold, Christine, Christine Pink, Dr. Sharpe, Distinction, Felicity, Golden Christine, Mrs. Forsyth, Mrs. Pethers, Gluck, Empress, King of Anemones, Baron Beust, White Globe, Empress Eugénie, General Bainbrigge, Guernsey Nugget, Jeanne d'Arc, Mrs. J. Crossfield, Mr. Brumlee, Mrs. Dixon, Mrs. W. Shipman, Nil Desperandum, Pink Perfection, Refulgence, Mdle. Cabrol, Fernand Feral, Boule d'Or, Mrs. Sharpe, Mrs. Haliburton, Prince of Wales, St. Patrick, Progne, Madame Bouchard, Rosa Bonheur, Agrements de la Nature, Ethel, L'Incomparable, Magnun Bonum, L'Africaine, La Nympe.

**SIX FEET HIGH.**—Golden Empress, Queen of England, Empress of India, Alfred Salter, Lord Alcester, Jardin des Plantes, John Salter, Lord Derby, Mabel Ward, Mr. George Glenny, Mrs. G. Rund'e, Novelty, Cherub, Eve, Emily Dale, Mdle. Madeleine Tezier, Madame Clos, Triomphe de la Rue des Châlets, Striatum Perfectum, C-rez, Duchess of Albany, Dormillou, Elaine, Fanny Bouchard, Jeanne Delaux, James Salter, Lady Selborne, Marguerite Marrou, Mrs. Mahood, Acquisition, King of Crimsons, Album plenum, Bouquet Fait, Beauty, Brouze Jardin des Plantes, Lady Carey, Venus, White Venus, Oracle, The Sultau, Madame Thérèse Clos, Cry Kang, Mdle. Moulise, M. Delaux.

**SEVEN FEET HIGH.**—Sirnia, Soliel Levant, Peter the Great, Mons. Ard-ne, Japonaise, Daimio, M. Barret, M. Tarin, Philias, Lady Margaret, Balmoreau, Comtesse de Beuregard, Comte de Germiny, Baron de Prailley, Beverley, Golden Beverley, Lord Wolseley, Prince Alfred, Princess of Wales, Mrs. Heales, Mr. Bunn, Red Gauntlet.

**EIGHT FEET HIGH.**—Belle Paule, Sir Stafford Carey, Fair Maid of Guernsey, Le Sceptre Toulousain, Thunberg, Madame Bertie Rendatler.

**TEN FEET HIGH.**—Madame C. Audiguiet.

—E. MOLYNEUX.

### LIVERPOOL—A GUIDE TO VISITORS.

PERHAPS more horticulturists will visit the city of Liverpool towards the end of this month, through the Royal Horticultural Society holding their great Show in Wavertree Park, than has ever before been the case in the history of the second city in the empire. On an occasion like this all who visit the "great Show" will be anxious to see all that is worth seeing in the city and neighbourhood. From past experience I know that much valuable time is wasted by strangers in a strange city, in finding out the best routes and places of interest. It is generally the case that not half is seen in the time at disposal as could be done if only they possessed some reliable guide to inform them where to go and how to save time with as little outlay as possible. On past occasions I have been in this predicament, and therefore understand the position in which all will be placed who visit Liverpool for the first time. I propose, with your permission, Mr. Editor, to write a few notes as a guide to all who need help in this matter.

It may be as well to state at the outset that passengers travelling by the London and North-Western Railway can alight for the Exhibition either at Edge Hill or Lime Street Stations, the first being within a few minutes' walk of the gates of Wavertree Park, and the other almost in the centre of the city. Passengers should come out of the station by the main entrance, cross the street, and then wait for the Wavertree Park tram, by which they can be conveyed close to the gates of the park for 2d., from this point the tents and implements will be visible. It may be stated that most of these trams have already printed in large letters on the front of them "To the Exhibition." There will be no scarcity of trams on this route, for already a considerable number of extra ones are running, in addition to the usual service which pass Lime Street station about every ten minutes. The large building on the opposite side of this station is St. George's Hall, which is open daily to the public and is well worth a visit. At the end of this street, or in William Brown Street, are arranged one after the other the Walker Art Gallery, Museum, and Free Public Library. The collections in these buildings deserve a visit by all who are interested in such matters and wish for some change from the garden and gardening. Just above the station is the Alexandra Theatre, where an evening may be pleasantly spent when other sights and places of interest cannot be seen.

Others travelling *via* the Midland, Great Northern, Manchester, Sheffield, and Lincolnshire Railways, as well as by the Cheshire Lines, will arrive at what is known as the Central or Ranelagh Street station. Not two minutes' walk from this station, on the right coming out, is the world-famed enterprising firm of Lewis & Co., the "friends of the public," as they term themselves or are termed. This establishment, nevertheless, is worth a visit if there are a few minutes or half an hour to spare, for it is undoubtedly one of the most wonderful and interesting establishments of its kind in Britain. Passing this, the visitor will find himself in Lime Street, and if a turn to the left is taken two minutes' walk will bring him to the point opposite Lime Street station, to which passengers arriving there have been directed to wait for their tram to convey them to the Exhibition ground. Re-tracing our steps again to the Central station a small street opposite will be noticed, which leads directly into Clayton Square, through which nearly all the trams pass for the Exchange and Pierhead. But in the Square in question there is the Prince of Wales's Theatre. If a turn to the right is taken out of this

Square St. John's Market will be seen, which is the principal flower and retail market in the city and which will be readily noticed by its quaint frontage. This is only a short street, which again leads to the point where we have advised visitors to wait for their tram. There yet remains the Exchange station in Tithebarn Street, into which passengers arrive who travel by the Lancashire and Yorkshire Railway Company's lines. The street named runs almost parallel with Dale Street. The last can be reached by passing through any one of the small cross streets, and from this street the tram for the Exhibition can be taken, as it passes down on its way to the point in Lime Street that has been previously mentioned. I have not the slightest doubt that visitors to Liverpool will find sufficient to interest them for the first day at the Royal Horticultural Society's great Show. The same route, however, is taken from the various points detailed for the Shipperies Exhibition, which can be seen from the grounds in which the "Royal" will be held. This must be visited, for it is one of the greatest and most interesting Exhibitions that has probably ever been held in this country. The number of the exhibits are great and very varied. It is so gigantic that it is utterly impossible to examine or even to see half the exhibits in the space of a day. It will be finished by the end of the month, and will then be at its best. The display within the grounds is not destitute of horticultural interest; on the contrary, some time could be profitably spent in noticing the collection of Alpine and other plants on the rockwork, which has been formed in the grounds by Mr. William Clapham, Bramhall Park, Stockport, to whom laying out a good portion of the grounds has been entrusted. This work has been well executed and the grounds rendered very attractive considering the difficulties that have been contended with and the state it was in only a few months ago. It must not be forgotten that the Exhibition grounds were a series of pits from which clay had been taken for bricks. Great credit is also due to our local florists and nurserymen who have largely contributed to the beauty of the grounds. Messrs. R. P. Ker & Sons, The Liverpool Horticultural Company, Messrs. T. Davies & Co., Turner Brothers, Messrs. F. and A. Dicksons & Sons, Chester, Caldwell & Sons, Knutsford, Messrs. J. Dickson & Sons, Chester, and others have each undertaken laying out and furnishing a large portion of the grounds. These contributions to the Exhibition are by no means its least interesting feature. I do not intend to particularise the various groups and their arrangement on the present occasion, but at some future time they shall be referred to again. Particular attention must be paid to the bank behind the rockwork, which has been sown with grass seeds by Messrs. Webb & Co. The portion of the grounds laid with turf cannot be compared with this bank for freshness and beauty; it has been well furnished and in a very short space of time.

That great engineering achievement the Mersey Railway Tunnel cannot be passed, for it is a work of vast magnitude, and should be seen by all who visit the city. The station is in James Street, about two minutes' walk from the Exchange, and only a very short space of time will be required to pass through it and back again. The intelligent and observant will be well repaid for the time spent and the outlay of a few pence. If the visitor desires, when he has reached Birkenhead he can examine the Park before returning; but for this purpose I advise a change—that is, when James Street station has been again reached, to turn to the right when passing out of the station into the street, which will lead to the landing-stage, which is said to be the finest of its kind in the world. This can be inspected, and then a trip taken by the Woodside Ferry steamer to Birkenhead for 1d. Directly the pay-gate is passed through a tram station will be noticed, and from this point the tram should be taken to the Park. This Park was laid out by Mr. Kemp, and is said to be probably the finest park in this country. It should be visited by all gardeners who have not seen it, for some hint or idea in landscape gardening may be gleaned. Those who visit it with this object in view will be abundantly repaid for their time and trouble. It is indeed a poor park or garden from which something cannot be learned, but in the park in question many a valuable idea may be gathered, and a fitting opportunity some day may present itself for putting them into practice.

A few pleasant hours may be spent by visiting New Brighton. The steamer leaves the landing stage every half hour, and returns at intervals of the same space of time. The trip takes twenty minutes each way, and the fare is 3d.

The Palace Winter Gardens which are on the beach are worth seeing, for in addition to glass houses filled with plants and fruit there is a remarkably fine grotto, a collection of birds, and always some kind of amusement. I am certain that Mr. C. Finnigan, the gardener in charge, will be very pleased to show the houses not open to the public to all gardeners who who may desire to see them, if they inquire for him after passing in at the entrance.

The docks must be inspected to form any conception of their magnitude. There is about eight miles of them altogether. A bus, or the "dock tram," as it is termed, runs the whole length, starting from near the landing stage, and running to the last one that has been open, for 2d. It is easy to find out the exact point this bus starts from by making inquiries at the landing stage. To inspect the docks it is the best plan to take the bus down, and walk back towards the city. However, those who visit the docks will have seen enough of them long before they reach the point from which they started, but when tired the bus can be taken again to complete the return journey. Any of the large Atlantic steamers that may be in dock about that time can be inspected by calling and asking for a ticket at the various offices in Water Street. This street runs in a direct line from the Exchange to the landing stage. The steamers in at that time can be found out by consulting the local daily papers. There is nothing about Liverpool which gives greater pleasure

to strangers than a thorough inspection of the extensive docks and thousands of ships from all nations that are crowded together in them. Some idea of the carrying trade of the nation is gained, and the commerce of a great and busy seaport like Liverpool.

For those who desire a thorough change from the garden and gardening, no more fitting opportunity could exist for a day's trip than to proceed by steamer to Llandudno or the Menai Straits. These steamers leave the landing stage daily, Sundays excepted, at 10.45 A.M., and the return fare is 4s., or 4s. 6d. respectively. If a longer sea voyage is desired, the Isle of Man may be selected. This will take up at the least nearly two whole days. The fare is equally reasonable, and the steamers leave the landing stage daily at 1 P.M., and return the following morning from Douglas at 9 A.M.

The principal object of gardeners when visiting a neighbourhood is to inspect all within reasonable distance that is of horticultural interest. It is wise and beneficial to have a change, hence the various features and enjoyable excursions are pointed out. I shall, however, in a future issue point out what gardens, nurseries, and parks within reasonable distance are worth visiting.—A CITY MAN.

### RUSHING INTO PRINT.

PERMIT me just to say, in reply to your "W. P. R.," that seeing I before said that he had probably no connection with my "W. P. R.," one would have thought that a single denial to the same effect on his part would have been sufficient, if he noticed it at all; but his innuendoes and the dates and circumstances, &c., which he gives, coupled with his initials and the qualifying statement that he fails to identify himself with the "incidents" related by me only "inasmuch" as anything he has written about others "has been free from exaggeration, and strictly accurate," gives one the impression that there may be more between the lines and not so many "W. P. R.'s" in the world after all. My story may be old, but it is true (it is exactly the age he states as the period since he was foreman in a lord's garden), and I would add that your "W. P. R.'s" newly manifested reluctance to "take up your space and his own time" on this topic, after occupying so many of your columns without hesitation, and spending so much of his own time investigating matters he does not appear to have any business with, outside of a desire to "rush into print," suggests reflections that need not be here expressed. I do not admire his late attempt to pillory in the public prints a gardener in a private place (whose identity may be guessed by many) because of private transgressions, the true particulars of which "W. P. R." cannot vouch for himself, and I think you have done right to expunge the personal element from the discussion; but under the circumstances, my little story about my "W. P. R." was not, I think, inappropriate if old, though it does not seem to strike your "W. P. R." in the same light.—HEAD GARDENER.

### MESSRS. J. VEITCH & SONS' ORCHIDS.

THE orchidic triumphs of the Veitchian establishment would form a valuable and instructive record, and most of the numerous visitors who inspect the surprising collections at Chelsea must feel that there is an historical interest attached to them quite apart from their individual or collective beauty. Not only have great numbers of Orchids amongst other plants been introduced by the collectors dispatched by this firm either from Exeter or Chelsea, but they have still farther increased the numbers of cultivated Orchids by the many beautiful hybrids raised in their nurseries. Scarcely a season passes without some valuable addition is made in this way, and all orchidists now look with much expectant interest for the Veitchian novelties. The merits of many of these have been amply proved, and such plants as *Calanthe Veitchi* and *Cypripedium Sedeni* are favourites in gardens innumerable, while many others are destined to obtain a similar popularity as their numbers increase. The work thus performed in hybridising is invaluable, and the interesting paper read by Mr. Harry J. Veitch at the Orchid Conference last year detailed some of the difficulties that have attended the experiments and the successes that have rewarded their efforts.

June is one of the best months that could be selected for a visit to the Chelsea nursery, for the Orchids are flowering profusely, and there are also many other floral attractions. With the Orchids we are, however, now chiefly concerned, and a few notes upon these will give an idea what constitute the leading features. Visitors to this nursery now generally first inquire for the great *Cattleya* house which is so widely famed as the finest structure of its kind, and those who have seen it during the past week will not readily forget the effect. The house is 132 feet long, a lofty spacious structure occupied throughout with *Cattleyas* and *Lælias* in magnificent vigorous health, and bearing at the present time a total of over 1000 flowers, mostly grand varieties of *C. Mossii*, *C. Mendeli*, and *C. gigas*. These are very numerous, the blooms large, the colours bright and varied, some forms being as distinct as those which formerly received names. This practice is now discontinued, and the comparative merits are indicated by crosses, which is far preferable. It is not surprising that *Cattleyas* have become such favourites within the past few years; they are so free in flowering, produce such handsome blossoms, and are distinguished by such rich and soft crimson shades, that no other Orchids can equal them in these respects. Of *Lælia purpurata* large numbers of plants are grown, the varieties choice and beautiful, those with the pure white sepals and petals and crimson lips having a very striking appearance. The principal portion of the plants in flower are arranged to form

a bank on one side of the house, and they produce a charming effect, but there are numbers of other plants in flower scattered through the house with them; besides those already named being *C. Warneri*, *C. lobata*, *C. elegans*, and *C. Skinneri* all in capital condition. The last named is a much-valued plant, especially as its flowers show extremely well under artificial light, which probably is partly due to the crystalline lustre of the sepals and petals. A large and well-grown plant of *Cymbidium Lowianum* at the corner of the central bed has five long racemes of nineteen to twenty-three flowers each, or a total of about 100 flowers. A few *Oncidiums* and other Orchids are also introduced to vary the display; the lovely *Odontoglossum citrosum*, with its pendant panicles, adding materially to its beauty.

The central range of houses, which is entered from the fernery, is next visited, and there the plants in flower are very numerous in the several divisions. *Dendrobiums* are particularly abundant, some of the most useful being represented. The golden *D. chrysotum* and *D. suavisimum* are very bright; in contrast with them being the white *D. Jamesianum* and *D. infundibulum*, the two latter being occasionally mistaken for each other, but they can be readily distinguished by the colour of the blotch in the centre of the lip, which is deep orange in *D. Jamesianum* and of a lighter yellowish tint in *D. infundibulum*. *D. crystallinum*, the ivory white *D. eburneum*, the curious and delicate *D. tortile*, the white, free, and useful *D. Deari*, and the handsome white and gold *D. thyrsoiflorum* are attractive; but perhaps the most pleasing of all is the floriferous *D. Bensoniæ*, which is most varied, the sepals and petals pure white, but the yellowish lip has a deep maroon blotch at the base, which differs considerably in size and is sometimes divided, so that there are two blotches. This useful and easily grown *Dendrobium* ought to be much more generally grown, for it is one of the most distinct and best. With such other well known forms as *crassinode* and *crystallinum* it was introduced by Messrs. Veitch & Sons through their correspondent Lieut. Col. Benson. In an adjoining house are some good plants of *Anguloa Clowesi*, which has been fancifully named the Cradle Orchid, though others have also termed it the Tulip Orchid, and it may be imagined that if there were any real resemblance to such diverse objects as Tulips and cradles its appearance would be rather peculiar. Its bright yellow flowers are, however, very notable, and they last for a great length of time. The Butterfly *Oncidium*, *O. Krameri*, is an extremely remarkable mimic, and one plant is in uncommonly good condition with seven scapes of large richly tinted brown and gold flowers. The white drooping *Angraecum Chaillanum*, the old but beautiful *Camarotis purpurea*, and the brightly flowered but seldom seen *Broughtonia sanguinea* constitute other attractions.

At the top of this range is a house of *Cypripediums* and *Phalænopses*, with a brilliant bank of the orange-scarlet *Epidendrum vitellinum majus*. Amongst the *Cypripediums* the long-petalled *Stenei lævigatum* and *selligerum* are very handsome; the pretty white *C. niveum*, and those fine forms of the *C. superbiens* or *Veitchi* type *C. ciliolare* and *superciliare*, are also in flower, together with the majestic *C. Lawrencianum* and the lovely hybrid *C. Schoederae*, though the rosy-tinted flowers of the latter are now past their best. The white or softly tinted *C. Sedeni candidulum* is still flowering freely. Of *Phalænopses* there is a pretty display of the small-flowered *P. sumatrana* and its pretty relative *P. Mariæ*, which also bears some resemblance to *P. Luddemaniana*, though quite distinct. It is one of Mr. F. W. Burbidge's discoveries, and bears his wife's name. *P. violacea*, *P. amabilis*, and *P. rosea* are flowering with *P. speciosa*, the latter on a hock, with two spikes of four and five flowers each. *Cœlogyne Massangeana*, *C. Dayana*, and *Dendrochilum latifolius*, a broad-leaved species with long racemes of flowers, and the new *Oncidium Jonesianum* are equally noteworthy.

The cool-house is highly attractive, some hundreds of racemes of the best *Odontoglossums* constituting a superb display. *O. Pescatorei*, *O. crispum*, *O. cordatum*, *O. maculatum*, *O. vexillarium*, *O. luteo-purpureum*, *O. nebulosum*, and *O. gloriosum* are the principal species, some grand varieties of these being represented. The bright yellow *Oncidium concolor*, the orange-scarlet *Epidendrum vitellinum majus*, the crimson *Masdevallias* of the *Harryana* type supply agreeable relieving tints.

In other houses, *Gloxinias*, *Imantophyllums*, and the showy *Anthuriums* afford exhibitions of special beauty that should be seen by all interested in these plants.

### FIRM SOIL THE BEST.

In your last issue, on page 450, "Kitchen Gardener" writes a very sensible article. I am of the same opinion as he, for I think there is a great number of plants ruined by not being potted firmly enough. Take for instance Strawberries, which require very firm potting, yet I have lived with some noted gardeners that would not have their Strawberries potted firmly, but I have had the fortune to live in a place where a large number of Strawberries were forced, and where they were potted as firmly as they possibly could be; hence I have seen both sides of the question, and have had the opportunity of watching the results. I have found that where loose potting was done they not only formed very indifferent roots, but of course made very poor crowns, and then when forced in the spring the result was a very poor crop of fruit, when, on the other hand, those that were potted quite firmly always formed thick sturdy roots and well ripened crowns; and as it is well known unless the plants are well ripened and in a healthy condition there can be no good fruit when forced.

Again, even such tender-rooted things as *Mignonette* enjoy firm potting, although I have, as a rule, found this plant potted rather loosely but I have seen very fine plants grown in 10-inch pots that were so firm

that not the least impression could be made on the surface with the thumb. As regards kitchen gardening, I think many gardeners would meet with much better results if the soil was made firmer when the crop was sown or planted, especially in light sandy soil. Onions, for instance, never do so well in a light loose soil as they do in a moderately heavy and well firmed soil; but at the same time the soil should not be too rich, for I think much better bulbs are grown in a moderate soil; although if not quite so large, they are much firmer and therefore better for keeping.

I also agree with your correspondent in having the soil moderately firm for Carrots, Parsnips, &c., although it is not, as a rule, practised, but I have found that in "exceptions to the rule" such vegetables have turned out with much better and cleaner roots.—AN OUTSIDE FOREMAN.

### MEALY BUG.

OF all the insect pests that infest plants this is the most troublesome. It is so uninviting, that the only member of the feathered tribes that I have observed will have anything to do with it is the blue titmouse, which, along with the long-tailed titmouse, is so useful in clearing Apple and Pear trees of mussel scale, but this has invariably succumbed to its partaking of the mealy bug. Several times have I had the blue titmouse entering stoves by the ventilators to find the mealy bug, and in every instance the birds have died. Whether poisoned by the mealy bug or through the confinement I am not prepared to state with certainty, but Robins survived for weeks in the same structures, and they never, that I could see, would have anything to do with this insect.

Mealy bug is known to everyone cultivating plants requiring a stove or an intermediate temperature, and though not increasing so rapidly in a greenhouse, is by no means uncommon in those and conservatories, in fact it is often seen on plants at exhibitions. A correspondent, "Observer," many years ago, could see nothing for it but starving the insects out, and he wrote as one having had much to do with mealy bug in plant and fruit houses. I have never tried this, which seems a "perfect cure," through want of opportunity, but it appears reasonable, only it is difficult to persuade employers that the only certain method of eradicating mealy bug from stoves and vineries, where the pest has had its home for years, is by starving out. I know the roofs of vineries are more fixed of late than they were some years ago, most old gardeners considering that rain from the clouds was particularly invigorating and cleansing, and we know equally well that Vines were syringed much more frequently than now. Bug in vineries and on Pines was considered a great humiliation. To clear it from the Vines no trouble was considered too great. Compositions of soot, lime, sulphur, tar, tobacco water, nux vomica, urine, clay, &c., were requisitioned; insecticides; no end of patented "cure alls;" and yet mealy bug is as lively as ever.

Mealy bug does not much infest plants in greenhouses or conservatories. They are kept too cold and too moist, and there is not much cause for anxiety in cool vineries, though it is more to be dreaded in the Vines than in the climbers of the conservatory, as the season of the Grapes ripening necessitates a dryness and warmth highly favourable to the insect. We no sooner pass from houses of Cape, Chinese, or New Holland plants, than we have to face this loathsome pest. Mealy bug swarms on Gardenias and Stephanotis; it likes no place so well as the choicest cluster of Grapes, and delights in showing itself beneath the recurved leaf-crowns of Pine Apples. It glories in feasting on Melons; indeed the difficulty is not so much as to what it does like, as to what it does not.

The mealy bug's natural enemy, as I take it, is water. For plants infested with mealy bug I advocate thorough cleansing with water, forced upon them so as to dislodge the insects, and at a not less temperature than 120°, nor exceeding 140°, and keeping it from the roots by tarpanlin or other waterproof material in the case of plants in borders or pots or tubs that cannot well be laid on their sides. The sudden heating kills the insects it comes into direct contact with; at any rate, it dislodges them. Plants in pots of moveable size may be leaned over a wide shallow vessel, and the plants turned round can be syringed with the hot water both on the under and upper side of the leaves, there being no excuse for not clearing the mealy bug from every part of the plants. This only needs repeating to entirely banish mealy bug; but the bug having possession of the house it will not be long before it finds its way to the plants, and more work will be made, for as the house is so are the inmates, and *vice versa*. Limewashing walls and clearing out spent fermenting materials—in fact, thorough cleanliness all round, is the way to excel in the cultivation of plants. Syringings, to be of use, must be thorough, or they are ineffectual for the destruction of insects. Some plants cannot well be syringed, such as bulbous and other plants; but they can be sponged with water, and if this is done with care and frequently mealy bug cannot make headway. Plants with hairy leaves, such as Gloxinias, Achimenes, Tydæas, &c., will not bear hot water, and sponging is out of the question, but the "catch and kill" system never fails of its object. Take any plant infested with mealy bug and stand it outdoors when there is a prospect of a thorough drenching from thunder rain, and it will derive more cleansing benefit than from a week's sponging and brushing with insecticides. I do not know what water contains besides ammonia as it comes fresh from the clouds, but I do know that a thorough day's rain cleanses foliage of insects better than any insecticide, and is far more beneficial to the roots than artificial waterings. Much more might be written about plants and fruit trees under glass having the benefit of exposure to rain and as much cold as is safe.

I have no wish to decry insecticides; they are useful, and as a rule not costly. To single out any would obviously be invidious; but there are remedies within the reach of all that I may allude to without fear of

jealousy. Next to water the best mealy bug destroyer is no doubt ammonia, allied with the potash and soda as present in soapsuds. The soapsuds are so variable in strength as to be only available for the most hardy plants, and ammonia is so volatile as to be difficult of application in safe quantities. We may, therefore, dismiss it for the present, though I hope at some future time to refer to it; only I would like to remark that the ammonia vapour we find so useful against red spider is also valuable as an agent in ridding houses of mealy bug. Oils next claim attention. Petroleum has a high reputation as an insecticide which it justly deserves, and as a destroyer of bug it is most useful. The difficulty is mixing it. Soapsuds when clear are good, but these are not always obtainable, so that we can easily make a solution of softsoap 2 ozs. to the gallon and quarter of an ounce soda per gallon. To every four gallons of this use a quarter of a pint of petroleum. This will float, but by stirring briskly with a broom-handle, or by filling a syringe and expelling the liquid into the vessel sharply, so as to force the petroleum into the soapy solution, it can readily be applied by a second person to the infested plants. If it must be done by one person, then alternate ejections must be made into the vessel and on to the plants. These should be laid on their sides over a tub or tin large enough to receive the mixture as it drips from the plants, turning them over or round so as to thoroughly wet every part of the foliage on both surfaces and every part of the wood. The mixture should be used as hot as the hand can bear, and kept from the roots as much as possible. Shake the plants over the vessel so as to free it of superabundant moisture and prevent much running down to the roots when stood erect, and stand aside until the whole of the plants are gone through, and if possible in another structure until dry. The house must then undergo a thorough cleansing, syringing the whole of the roof, stages, everything with the stuff except the glass parts, which should have the softsoap omitted, driving it into every hole and crevice. Allow to dry; then if there be any bug paint the whole of the woodwork with petroleum, rubbing it well into every crevice, leaving no part untouched, and limewash the walls. The petroleum will soon pass off, when the plants may be examined, and if there is any bug left repeat as before, before returning to the house. It would be a good thing to have the house painted if it need it, not being afraid of turpentine. Examine the plants once a week. If the bugs are few the "killing" system will answer, but if they are increasing repeat the petroleum application, which, however, will not be required within six weeks, and more distantly in winter. It must, however, be followed up if a riddance is to be effected. Plants out of pots are worse to deal with, but they may be loosened from the trellises.

We cannot make any use of the petroleum in destroying mealy bug on Vines during their growth, and up to the clearing off of the Grapes. Where bug, however, has possession, no satisfactory Grapes will ever be grown until it is destroyed, hence the Grapes should be cut so that the Vines and house can be thoroughly cleansed, and in the manner advised for plants. The Vines should be lowered from the trellis so as to wet the leaves on the upper as well as lower surfaces, and repeated three or four times in bad cases, allowing to become dry between each, and this seen to again before the leaves fall will be the means of preventing any from seeking winter quarters. Thorough cleansing of the Vines and house must be attended to at once after the foliage is down, removing the top few inches of the border and replacing with fresh material. Before the Vines are started, syringe them with the petroleum, omitting the softsoap, as that is best kept off the glass, and repeat before the buds have burst their wool-like envelopes. Syringe well in spring, or after starting, with water, one good cleansing being of more value than a dozen hedewings, and repeat after setting and thinning. We need not fear sediment if only clear rain water is used. In addition, make a close examination of the Vines and foliage once a week. A small phial with a piece of string round the neck and a wire hook will make all handy of operating with methylated spirit. A small camel-hair brush or pencil dipped in it and applied to the bug will destroy it. This is the best plan of dealing with bug in bunches of Grapes.

About a tablespoonful of turpentine to a quart of water, in which half an ounce of softsoap has been dissolved, makes an excellent mealy bug destroyer, but it is difficult to keep it mixed, requiring almost constant agitation. It should be applied with a brush carefully to the infested parts only. Petroleum in the proportions given, with softsoap and soda, may also be used for cleansing plants of mealy bug, scale, &c.

More or less injury is inflicted on the foliage by the use of petroleum, turpentine, and other fixed oils, and when made soluble they lose their efficacy as insecticides, therefore we must submit to the injury. This, happily, when care is taken in its application, is slight. The petroleum seems to act injuriously by closing the pores, hence old leaves are brought down, their ripening being hastened; but the young foliage is not much affected, provided care is taken to keep it mixed with the water or soapy solution. When carelessly applied some parts will be covered with the petroleum whilst others are comparatively free; the foliage will be injured in the one case, and the insects will get off scathless in the other. The petroleum requires to be kept from the roots, as the fixed oils do not decompose, but retain their natural properties, consequently are injurious. With care and judgment in application petroleum is a cheap and efficacious insecticide, without equal, so far as I know, for the eradication of mealy bug. Brief allusion to the value of potash and soda in soapsuds has been made, the value of softsoap as an insecticide resting on those properties, and to which we must attribute the value of softsoap solutions in the destruction of mildew. Mention has also been made of ammonia, than which I think no more powerful insecticide exists, if we knew in what form and strength to use it. Alums have, I think, been used for some time on the Continent, and with success in the destruction of caterpillars,

aphides, and American blight. If the alum solution will destroy American blight there is little fear of its not freeing plants of mealy bugs. Both have protection, which render them difficult to reach with an insecticide. The white cotton-like substance exuded by American blight acts as a covering for the insects, and mealy bug is covered with meal, and forms cocoons of cotton-like substance in which the young are reared. The covering in both American blight and mealy bug are impervious to water unless applied with considerable force, which renders their destruction difficult, as the insecticide, to be of value, must be brought to bear upon the insects. An ounce of alum dissolved in boiling water, and cold added so as to make a gallon, may be tried, and its effect noted upon different insects and plants.

Sal ammoniac is also likely to prove useful against insects and mildews. It and sulphate of ammonia are soluble in water, and might be tried as insecticides at the rate of half an ounce to a gallon of water. The ammoniacal liquor of the gasworks is a valuable insect killer; diluted with sixteen times its bulk of water it ought to prove safe for most plants. These are mentioned with a view to encouraging experiments. Insecticides should act like rain—cleanse the foliage of insects and other impurities; clear the pores, so that the nutriment would be more highly assimilated, which, with the enriching the soil, would contribute to the increased health and vigour of the plants.—A YORKSHIRE GARDENER.

AT a general meeting of the ROYAL HORTICULTURAL SOCIETY held June 8th, Maxwell T. Masters, Esq., M.D., F.R.S., in the chair, the following candidates were unanimously elected—viz., Colonel Hugh Baillie, Johannes Bergmann, L. Bryett. Besides the above, Mons. A. Bleu was elected a corresponding member.

— MESSRS. JAMES CARTER & Co. send us specimens of their new AMERICAN KNICKERBOCKER RADISH, and invite us to observe that, although the plants have commenced running to seed, the root retains its edible properties, whilst all other kinds grown near it have become quite pithy and useless. They also point out that its great size must render it valuable to large consumers. We have never seen Radishes so large and at the same time so firm and crisp as the specimens in question.

— MESSRS. JOHN LAING & Co., Forest Hill, have sent us their gorgeous coloured plate of the Royal Family of Begonias, the varieties being alike remarkable for size, form, and colours. Such flowers could not have been anticipated by the most sanguine of hybridisers a few years ago, yet we believe there are some 7 inches in diameter now in cultivation.

— WE observe by the schedule forwarded to us that the BRIGHTON CHRYSANTHEMUM SOCIETY'S SHOW will be held on November 16th and 17th; also that substantial prizes are offered, notably in the classes for groups, in which the first prize is £5, and for forty-eight cut blooms £10, the remaining prizes in this class being £6, £3, and £2. Mr. Longhurst, Church Road, Hove, is the Secretary.

— THE annual displays of CALCEOLARIAS AT BEDFORD HILL, BALHAM, are always worthy of note, not only on account of the admirable manner in which the plants are grown by Mr. Rapley, but for the excellence of the varieties. The plants are not quite so numerous and large this year as usual, the long winter proving inimical. There is, however, no depreciation in the quality of the flowers; but, on the contrary, varieties of great richness and clearness have been added. Some of the pure yellow varieties are magnificent, quite out-distancing the once famous Cloth of Gold. Mr. Rapley is to be congratulated on his success in establishing such a fine strain of these handsome flowers.

— THE magnificent collection of ORCHIDS belonging to ARTHUR POTTS, Esq., HOOLE HALL, CHESTER, the fame of which has extended far beyond the provinces, is on view at the Eastgate Street premises of Messrs. F. and A. Dickson & Sons, Chester, during this, the yeomanry, week in that city. The collection is an extensive one, and Mr. Potts has generously thrown open his garden and grounds to those interested in horticultural matters. Tickets can be obtained free at Messrs. F. and A. Dickson & Sons. Exhibitions of this character are most interesting and in every way commendable.

— THE GARDENS OF THE INNER TEMPLE are now open to the public nightly from six until nine o'clock, the permission thus granted by the benchers being more especially intended for the benefit of the poor children inhabiting the surrounding closely populated neighbourhoods. Hundreds of these poor children may be seen every evening playing upon the large and well-kept lawn in the centre of the gardens, and it is gratifying to state that, although so many enter the gardens nightly, there has not been a solitary instance hitherto of damage or injury to the trees, shrubs, or plants.

— THE Richmond Local Board have decided to purchase the Duke of Buccleuch's estate, which was recently offered for sale at £30,000, and to reserve a portion of it for a public recreation ground. It is situated upon the slope immediately beneath the terrace, and if the whole of it had been built upon as was intended the delightful and famous prospect would have been deprived of the greater portion of its beauty. The local magnates who have favoured the scheme deserve the thanks not only of the townspeople, but of the public generally.

— MR. W. N. CRAIG WRITES:—"There is at present in bloom at Park Side Gardens, Kendal, the residence of J. E. Openshaw, Esq., a fine collection of HERBACEOUS CALCEOLARIAS. The plants number about 100 from 3 to 4½ feet in diameter, and are perfect pictures of health and vigour. The display is well worthy of a visit, and once seen will not be readily forgotten. The condition of the plants reflects the greatest credit on the painstaking head gardener (Mr. T. Railton), who has made Calceolarias a special study, and appears to have achieved complete success in their culture." The flowers received are well grown and very diversified and bright in colour.

— WE have received the well arranged and comprehensive schedule of the HULL, EAST RIDING, AND NORTH LINCOLNSHIRE HORTICULTURAL SOCIETY. The Exhibition will be held in the Hull Botanic Gardens on July 14th, 15th, and 16th. We are informed that two gold and two or more silver medals will be awarded. The chief class is for ten stove and greenhouse plants in bloom (Orchids excluded) and six ornamental foliage plants, the prizes being—first, £15 and the Society's gold medal; second, £10; and third, £5. Other good prizes are offered in the open classes and invite good competition. The schedule numbers 127 classes in six sections, and there are to be trials of mowing machines and garden engines. A large and diversified exhibition may be expected. The Right Worshipful the Mayor of Hull (Mr. Alderman Williams) is President of the Society; George Bohn, Esq., C.E., Chairman of the Committee; and Messrs. E. T. Sharp, James Dixon, and P. MacMahon, Curator of the Botanic Garden, Honorary Secretaries.

— A CORRESPONDENT writes:—"It is customary with many who cultivate choice exotics to despise our native flowers, probably because they are common and do not possess any pecuniary value. Happily there has been some alteration in taste lately, and in floral decorations these simple familiar flowers are occasionally employed in preference to the more brilliant and costly rarities. But to thoroughly appreciate such plants they must be seen in their native luxuriance, as wildings and in masses. At this time a common aquatic plant, RANUNCULUS AQUATILIS, is flowering profusely, and in some places it has a remarkable appearance. This is especially so in one of the lakes in Richmond Park, a large portion of which is covered with its pure white flowers. At a little distance on a still day we might imagine that it was a sheet of clear ice lightly covered with freshly fallen snow. It would no doubt be scouted as an absurd notion to propose establishing such a weed in lakes or shallow water, nevertheless it would add to their beauty in some places."

— DURING the recent riots in Chicago a store was sacked containing a quantity of alcoholic beverages; amongst these were, however, some bottles of WINE OF COLCHICUM, which somewhat resembles sherry in colour, but is a deadly poison. The consumption of this liquor caused the death of eight persons, and others are not expected to survive. The Meadow Saffron, Colchicum autumnale, is well known to be one of our most poisonous plants, very acrid narcotic properties being present in the bulbs, and preparations of these have been employed in small quantities for medicinal purposes, especially in the treatment of gout and rheumatism. It is said that "the Turks infuse the flowers in wine to add to its inebriating effects, and in autumn the peasantry of Carniola eat the bulbs with impunity."

— GARDENING APPOINTMENT.—Mr. Jesse Jones, late foreman at Brynkinalt, Chirk, near Ruabon, has been appointed gardener to C. H.

Day, Esq., Terrace House, Southampton. Mr. J. Garrett, who for several years has had charge of the floral garden and ornamental department in the Royal Gardens, Kew, and was formerly of the Royal Horticultural Society's Gardens, Chiswick, has been appointed head gardener to A. B. Mitford, Esq., C.B., Batsford Park, Moreton-in-Marsh, Gloucestershire.

— AT the meeting of the ROYAL METEOROLOGICAL SOCIETY, to be held at 25, Great George Street, Westminster, on Wednesday the 16th instant, at 7 P.M., the following papers will be read:—"Note on a Sudden Squall, January 13th, 1886," Robert H. Scott, M.A., F.R.S., F.R.Met.Soc. "The Floods of May, 1886," by F. Gaster, F.R.Met.Soc., and W. Marriott, F.R.Met.Soc. "On Atmospheric Pressure and its Effect on the Tidal Wave," by Capt. W. Nelson Greenwood, F.R.Met.Soc. "Meteorological Results at Levuka and Suva, 1875-1885, with Notes on the Climate of Fiji," by J. D. W. Vaughan, F.R.Met.Soc.

— FROM an abstract of the reports of the Gardening Societies forming the YORKSHIRE ASSOCIATION OF HORTICULTURAL SOCIETIES we find the Barnsley Society numbers 110 members, the Leeds Society 133, the Rotherham Society 48, the Sheffield Floral Society 90, the Hallamshire Society 40, and the Wakefield Paxton Society nearly 200 members. The meetings of this Society are held at the Saw Hotel, Westgate, every Saturday evening at eight o'clock, when lectures or essays are given. One of the principal features of the Society is the library, which contains about 300 volumes of scientific and practical works. During the summer an exhibition of cottagers' window plants and competitions for naming wild flowers is held, which gives great encouragement to the working class and school children to cultivate and study flowers. The Rev. F. D. Horner's excellent address on the objects of the Association and lecture on the Auricula are incorporated with the Report.

— ACCORDING to the ABSTRACT OF THE AGRICULTURAL RETURNS we find that 197,539 acres were under fruit culture in Great Britain in 1885—an increase of 2816 acres over 1884. The area of market gardens last year was 59,473 acres, an increase of 6698 acres over the year preceding. Nursery grounds are represented by 12,594 acres in 1885, an increase of 82 acres on 1884. The increase under fruit culture in England is 2587 acres, in Wales 67 acres, and in Scotland 72 acres. In England there was an increase of 6022 acres of market gardens over the preceding year; in Scotland an increase of 543 acres; in Wales a decrease of 67 acres. In nursery grounds the increase in England was 156 acres; but Wales shows a decrease of 3 acres, and Scotland of 61 acres.

— MR. WILLIAM CATTANACH, gardener to W. Connal Black, Esq. of Kailzie, Peebles, sends the following WEATHER REPORT FOR PEEBLESHIRE:—"The winter of 1885-86 will long be remembered in this locality for its length and severity. On September 1st the thermometer registered 10° of frost, killing all softwooded bedding plants. Autumn cuttings of Pelargoniums, &c., were scarcely to be had. Potatoes were killed. The weather was generally good till November 15th, when 10° of frost was registered; 16th, 17°; 17th, 17°; 18th, 20°. Fresh weather set in up to December 6th, when 8° was registered; 7th, 22°; 8th, 20°. Snow fell on the 9th; on the 10th, 22°; 11th, 14°. Weather very changeable with occasional frosty nights to the end of the month. Snow fell to the depth of 2 inches on the 29th. Total amount of frost for December, 120°. January began with storms of snow and rain, and all through the month was most remarkable for its changeableness from mild to extreme cold and frost, the lowest registers being on the 6th, 22°; 7th, 30°; 18th, 28°; 19th, 30°; 20th, 28°. Total amount of frost for January, 218°. Although the frost was not so severe in February as in January, it was of longer duration. Frost on twenty-four nights, with a total of 182° for the month. On the 3rd, 4th, and 5th there were respectively 14°, 27°, and 27°. There was a good deal of snow lying nearly all the month. March came in "like a lion;" on the 1st and 2nd snow fell to the depth of 12 inches, with a strong gale of wind from E.N.E., and up till the 18th the cold was as intense as in January, the total amount of frost for March being 157°. April was a cold month with strong winds; little or no frost until the 30th, when 8° was registered, and on May 2nd, 5°. All winter vegetables, such as Broccoli, Brussels Sprouts, Savoye, and even Leeks, were almost totally destroyed; also all autumn-sown vegetables, plants, Roses and Rhododendrons (ponticum), and common Laurels, have all suffered severely. Thermometer from Negretti & Zambra, London; registered at Kew; placed 3½ feet above ground facing north, and stands about 550 feet above sea level."

— A CORRESPONDENT sends us the following clipping from the *Standard* on BACTERIA in soil:—"The vindication of the character of

humus as an important source of crop nutrition, disparaged by Liebig, with his mineral theory, may be said to have resulted from the researches of MM. Schloesing and Muntz, continued by Mr. Warrington of Rothamsted. These chemists have fully demonstrated the important action known as nitrification, carried on by bacteria, to which the rame *Micrococcus nitrificans* has been given, the result being the production of nitrates in soils rich in organic matter or humus. In order to test the importance of this process of soil-fertilisation, or rather of conversion of elements of fertility from an inert state to one suitable for the nourishment of plants, Professor Laurent of the School of Horticulture, Vilvorde, Belgium, last year carried out some careful experiments, a record of which has been sent to us. Buckwheat was grown in pots under four different conditions—namely, 1, In natural soil; 2, In earth first sterilised, but afterwards inoculated with bacteria of the soil; 3, In sterilised soil; and 4, In sterilised soil with the addition of chemical manures. The conditions of the experiment were such as to exclude the inoculation of the sterilised soils in the third and fourth series. On the occasion of the first observation recorded the plants of the first series were the most robust; those of the second were healthy, but not as forward as the first; while the plants in the soil free from bacteria were comparatively puny; though those of the fourth set, having the aid of artificial manures, were superior to those of the third. The results were summarised in the following table, averages being given:—

Series.	No. of Leaves, Aug. 28.	No. of Leaves, Sept. 11.	No. of Flowers, Sept. 13.	No. of Seeds, Sept. 29.
1	9	15	126.33	94.67
2	6	13.17	128	96
3	3.62	6.62	58	23.5
4	4.6	10	88.4	66.75

Thus the action of bacteria in nitrifying the organic constituents of the soil had a greater fertilising effect than chemical manures consisting of nitrate of potash, undissolved phosphate, sulphate of lime, sulphate of magnesia, and sulphate of iron."

#### ROYAL NATIONAL TULIP SOCIETY.

THIS Exhibition took place as usual in the Gardens of the Manchester Botanical and Horticultural Society at Old Trafford, on the 5th inst., and proved to be much larger in extent than was at first expected, a greater number of flowers being staged than last year, but very many of them undersized. The cool weather of the preceding few days had saved the Rev. F. D. Horner's flowers for this exhibition; the blooms in his beds were generally past their best, yet he was enabled to show in good form, and carry off the leading honours of the day. It is worthy of note that in the extreme north of England Mr. Horner's head of bloom was nearly over; but in the Oldham district Mr. Barlow found great difficulty in obtaining enough blooms sufficiently forward to enable him to compete in a few of the leading classes. The flowers were arranged as usual on tables placed down the centre of the new show house, and the weather was all that could be desired.

The class for the best twelve dissimilar blooms, two feathered and two flamed flowers, brought eight stands, the Rev. F. D. Horner, Longfells, Carnforth, Kirby Lonsdale, being first with the following varieties in fine quality:—Feathered Bizarres: Commander and Dr. Dalton. Flamed do.: Sir Joseph Paxton, a variety that rarely fails to be good, and Orion, very bright. Feathered Roses: Nancy Gibson, in the best form, and Annie McGregor. Flamed do.: Annie McGregor and Mabel. Feathered Byblœus: Mrs. Cooper and Talisman. Flamed do.: Talisman and Duchess of Sutherland. In case of any misconception arising on the part of our readers we may state that a feathered flower only has no flame or beam of colour running up the centre of the petal, and that a flamed flower must of necessity be feathered also; also that the same variety, such as Annie McGregor or Talisman, for instance, may be shown as feathered only, and also as flamed, according to the character it assumes for the time. Second Mr. James Thurston, Springfield, Wolverhampton, with feathered biz. *Asclepias*, a new and bright-looking flower raised by the exhibitor, and Sulphur; fld. do., Dr. Hardy and Sir J. Paxton; feath. rose, Mrs. Thurston, a very pleasing and attractive flower; and Modesty; fld. do., Mabel and Lady C. Gordon; feath. byb., Adonis and seedling 89/3; fld. do., Talisman and Constant. Third Mr. D. Woolley, Millgate, Stokeport, with feath. biz. Mrs. Miller and Sir J. Paxton; fld. do., Merit and Sir J. Paxton; feath. rose, Julia Farmese, with bread and deep coloured feathering, and Heroine; fld. do., Annie McGregor and Mabel; feath. byb., Bessie and seedling; fld., Adonis and seedling. Fourth, Mr. W. Kitchen, Marple; fifth, Mr. John Wood, Royton.

In the class for six varieties, one feathered and one flamed in each class, there were eight competitors for eight prizes, the Rev. F. D. Horner being again first with feath. biz. Masterpiece; fld. do., Orion; feath. rose, Modesty; fld. do., Mabel; feath. byb., Mr. Cooper; fld. do., Duchess of Sutherland; a very pretty and even lot. Second Mr. D. Woolley with feath. biz, Sir J. Paxton; fld. do., the same variety; feath. rose, Julia Farmese; fld. do., Mabel; feath. byb. seedling; fld. do., Adonis. Third Mr. J. Thurston with feath. biz. seedling 76/7; fld. do., Sir J. Paxton; feath. rose, Modesty; fld. do., Lady C. Gordon; feath. byb., Adonis; fld. do., Talisman. Fourth Mr. John Wood. Fifth Mr. W. Kitchen. Three other prizes were awarded.

There was a class for six blooms, also for six Tulips, the competition confined to half-guinea subscribers, and seven stands competed. Mr. Hugh

Housley, Stockport, was first with feath. biz. Royal Sovereign, and fld. do. Sir J. Paxton; feath. rose, Leah; fld. do., Triomphe Royale; feath. byb., Violet Amiable; fld. do., Lord Denman. Second Mr. R. Wolfenden, Royton, Oldham, with feath. biz. Masterpiece; fld. do., Excelsior; feath. rose, Heroine; fld. do., Mahel; feath. biz., Violet Amiable; fld. do., Lord Denman. Third Mr. A. Fearnley, Lowton, Leigh. Third Mr. Wright Prescott, Lowton.

In the class for three stands of feathered Tulips there were fourteen competitors, the Rev. F. D. Horner being placed first with biz. Dr. Dalton, rose Modesty, and byb. Mr. Cooper—a charming trio; second Mr. D. Woolley with biz. Mrs. Miller, rose Mrs. Lea, and byb. seedling; third Mr. William Dymock, Stockport, with biz. Lord Randolph, a very fine new feathered flower, rose Mabel, and byb. seedling; fourth (exhibitor's name not given); fifth Mr. Thomas Wood; sixth Mr. James Knowles.

There were eleven stands of three flamed Tulips, Mr. James Thurston being placed first with good blooms of biz. Sir J. Paxton, rose Mahel, and byb. Adonis; second Mr. H. Housley with biz. Sir J. Paxton, rose Annie McGregor, and byb. Lord Denman; third Mr. J. Wood with biz. Sir J. Paxton, rose Aglaia, and byb. Lord Denman; fourth Mr. D. Woolley; fifth Mr. W. Kitchen; sixth Mr. Thomas Wood. Then there was a class for two blooms, one feathered and one flamed, for maiden growers only; and in addition to three prizes Mr. Barlow offers a quantity of valuable Tulip bulbs to all who enter. There were but two competitors, Mr. Jas. Wood being placed first with fld. biz. Dr. Hardy, and feath. byb. Maid of Orleans; second Mr. T. Holden with feath. and fld. roses, both unknown.

In a similar class open to all fifteen pairs of flowers competed. The Rev. F. D. Horner being again first with fld. biz. Orion, and feath. byb. Mrs. Cooper, both in excellent form; second Mr. H. Housley with fld. biz. Sir J. Paxton, and feath. biz. Royal Sovereign; third Mr. James Boydell with fld. biz. Sir J. Paxton, and feath. rose unknown; fourth Mr. W. Prescott; fifth Mr. J. Thurston; sixth Mr. R. Wolfenden.

Then came the classes for single blooms, and in these a large number were staged, from 100 to 200 in each of the six divisions. Feath. biz. from Mr. S. Barlow with George Hayward; second Mr. Prescott with Lord Lilford; third Mr. Jas. Knowles with Royal Sovereign; fourth Mr. S. Barlow with Sir J. Paxton; fifth Mr. Morris with Duke of Devonshire; sixth Mr. Barlow with Masterpiece; seventh Rev. F. D. Horner with Agamemnon, one of the late Mr. Hepworth's seedlings; eighth Mr. Barlow with William Wilson. Feathered Roses: First Mr. D. Woolley with Heroine; second Mr. S. Barlow, unknown; third Mr. Fearnley with Industry; fourth Rev. F. D. Horner with Charmer; fifth Mr. D. Woolley with Mahel; sixth Mr. Knowles with Heroine; seventh Mr. D. Woolley with Alice; eighth Mr. Morris with Industry. Feath. Byb.: First Mr. D. Woolley with seedling; second Mr. Knowles with Adonis, and third with Bessie; fourth Mr. Prescott with Guido; fifth Mr. Dymock with Lady Denman; sixth Mr. Woolley with John Hunt, and seventh with a seedling; eighth Mr. Kitchen with Violet Amiable. Flamed Biz.: Mr. Boydell with Bargate (Sir J. Paxton); second Mr. Thurston with Dr. Hardy; third Mr. S. Barlow with Excelsior; fourth Mr. R. Wolfenden with Mrs. Wilson; fifth Mr. Jno. Wood with Dr. Dalton; sixth the Rev. F. D. Horner with Sir J. Paxton; seventh Mr. S. Barlow, unknown; eighth Mr. Fearnley with Duke of Devonshire. Fld. Rose: First Mr. Housley with Triomphe Royale; second Mr. S. Barlow with Mahel, and third with Lady C. Gordon; fourth Mr. Housley with Leah; fifth Mr. Kitchen with Bertha; sixth Mr. Housley with Aglaia; seventh Mr. Knowles with Madame St. Arnaud; eighth Mr. Fearnley with Lady Crewe. Fld. Byb.: First Mr. Barlow with Adonis; second Mr. D. Woolley with Lord Denman; third Rev. F. D. Horner with Talisman; fourth Mr. W. Kitchen with Adonis; fifth Mr. Thurston with Duchess of Sutherland; sixth Mr. D. Woolley with Chancellor; seventh Mr. Thos. Wood, unknown; eighth Mr. Jos. Boydell with Westpoint.

The premier feathered Tulip was George Hayward, biz., shown by Mr. S. Barlow; the premier flamed flower, Orion, biz., shown by the Rev. F. D. Horner.

A large number of breeder Tulips were shown, and their striking self-colour contrasted markedly with the variegated blooms of the other sections. The Rev. F. D. Horner had the best six blooms, having of hizaries Dr. Hardy and Sir J. Paxton; roses, Thomas Parker and Miss Burdett Coutts; byblacemens, Glory of Stakehill and Alice Grey. Second Mr. John Wood with biz. Excelsior and Sir J. Paxton; rose, Industry and Mahel; byb. Surpasse Grande and Alice Grey. Third Mr. S. Barlow with Horatio and seedling 29/63; roses, Miss B. Coutts and Mrs. Barlow; and byb. Talisman and Glory of Stakehill. Fourth Mr. Kitchen; fifth Mr. J. Thurston; sixth Mr. D. Woolley. There were thirteen stands of three breeders, Mr. S. Barlow being first with biz. Horatio, rose Anne McGregor, and byb. Glory of Stakehill. Second Mr. J. Thurston with biz. Horatio; rose Anne McGregor; and byb. unknown. Third the Rev. F. D. Horner with biz. Sir J. Paxton; rose Thomas Parker; and byb. Alice Grey. Fourth Mr. A. Fearnley; fifth Mr. R. Wolfenden; sixth Mr. J. Boydell. The best hizarie breeder was Sir J. Paxton, shown by Mr. S. Barlow. Mr. Kitchen was second with the same; Mr. Thurston third with a seedling; Mr. Thomas Wood fourth with Sulphur; Mr. Kitchen fifth with Ariosto; Mr. Wood sixth with Strong's King; Mr. S. Barlow seventh with seedling 29/63, and Mr. Thurston eighth with Excelsior. Mr. Thurston had the best rose breeder in a seedling; Mr. Wolfenden was second with a flower unknown; Rev. F. D. Horner third with Hepworth seedling, fourth with Lady C. Grosvenor, and fifth with Miss Burdett Coutts. Mr. W. Prescott was sixth with Mrs. Barlow, Mr. H. Housley seventh with Mahel, and Mr. Thurston eighth with Annie McGregor. The best byb. breeder was Beauty of Whitechurch, from the Rev. F. D. Horner, and he was second with Glory of Stakehill, fourth with Talisman, and fifth with Miss Hardy. Mr. Barlow was third with Glory of Stakehill, and sixth with a seedling; Mr. Kitchen seventh with one unknown, and Mr. Thurston eighth with a seedling.

The premier breeder Tulip was Sir J. Paxton, shown by Mr. S. Barlow. A first-class certificate of merit was awarded to Mr. W. Dymock for feathered hizarie Lord Randolph from Adonis × Maid of Orleans; a fine and striking variety which broke from a very ugly breeder.

### MARÉCHAL NIEL ROSE.

THROUGHOUT April and May there is no Rose which can be grown in a greenhouse, or anywhere else, to equal this. Its richly coloured de-

lightfully fragrant blooms command the admiration of those who are accustomed to see perfectly grown Roses. It is by no means, however, an easy matter to grow it successfully, and I have had many failures with it. Eight or nine years ago I planted one near the back wall of a lean-to Peach house. It was trained between the ground and the trellis to which the Peach trees are tied, a space 4 feet in width and 40 feet in length. In two years after planting it had filled the whole of this space, and the next spring it produced over 500 good blooms. Our satisfaction was complete, but it did not last long, as the plant immediately began to assume an unhealthy appearance, and in less than six months it was dead. Lack of attention was not the cause of this, and to this day I cannot account for its death. Others, I might almost say dozens, have been planted in the position this one occupied, but not one of them has proved what I should term a success. They grow a little, begin to look poorly, and then die; but I think I am pretty sure of the cause. Most of the plants have been budded on the Briar or Manetti, and it is at this union the evil arises. There is generally a swelling or lump there; the bark over this cracks and cankers, and the further progress of the plant ceases. This I feel sure is the cause of 90 per cent. of the deaths of Maréchal Niels, and I have made up my mind finally that I will never plant another excepting those growing on their own roots. We have several plants of the latter that are all we could desire them to be. They have grown very freely for several years, and seem likely to continue to do so. During the last month they have thrown up some young sucker-like growths from the root, which are now 5 feet in height; and as these will soon scramble over the roof and become hard and matured by the autumn they will bloom freely next spring.

Apart from having it on its own roots there is another secret in growing this Rose, and should be observed by all. It only consists in giving the roots a deep cool soil. The plant we have just mentioned as having made growth 5 feet in length lately is in a cool bed of soil 3 feet in depth. Everyone cannot bud Roses, but all may propagate them by means of cuttings, and I would advise those who wish to possess Maréchal Niels of the right sort to put in a few cuttings at any time during the year, more especially during the spring and autumn.—J. MUIR, *Margam*.

### VANDA CRISTATA.

AT the Orchid Conference, South Kensington, last year, Mr. J. Roberts exhibited a group of varieties from the Gunnersbury collection, and one of the plants which attracted most attention was the curious *Vanda cristata* shown in fig. 87 which was sketched from Mr. Roberts' specimen. Though it was described by its discoverer, Dr. Wallich, as an extremely beautiful species or in similarly eulogistic language, it scarcely merits so much unqualified praise when we have so many other handsome species to compare it with. It deserves notice, however, for its distinctness, and the flowers both in form and colouring are rather pretty. In habit it has been compared to *Vanda roxburghii*, and like other *Vandas* it has the leaves strangely notched at the points. The flowers are borne two or three together. The sepals and petals narrow, green; the lip striped with bright yellow and red, divided at the apex with the side lobes diverging.

The plant was found in Nepal growing upon trees, but it succeeds well in pots under cultivation, and requires the temperature of the warmest house.

### CULTIVATED VIOLETS.

(Continued from page 447.)

**MULCHING.**—In order to lessen radiation and evaporation a mulch of manure should be given between the rows and plants, bringing it close up to the neck or collar, but not so as to bury the centre. A covering an inch thick over the ground will be necessary, and it ought to be applied from the middle of June to the early part of July. Sometimes the weather is so dry and hot that it is advisable to mulch earlier, so that the cultivator will need to exercise his judgment, and be ruled to a certain extent by the weather and the condition of the plants. It is of primary importance that they be kept in progressive growth, and free from red spider. The mulching is best applied after rain, or if given in a dry time water well after the mulching in preference to putting it on after watering. The remains of an old Mushroom bed, leaf soil, &c., are good substitutes for manure. Cocoanut-fibre refuse and the short grass resulting from lawn-mowing are available for mulching. It may be repeated at intervals through the summer, but it is not desirable to have the mulching thicker at any time than a couple of inches.

**Watering.**—The plants ought never to be allowed to become distressed by lack of moisture. Not only must water be given until they become established, but it must be given whenever the weather is dry; but after the plants are mulched it will not be needed so frequently. It is best given through a coarse-rose watering pot and over the foliage, and should be applied in the evening or on a cloudy day. A good soaking once a week in very hot dry weather, or at more distant intervals according to circumstances, is far better than sprinklings every evening.

**Feeding.**—A top-dressing of scot may be given in three weeks to a month after planting, and at the rate of half a peck per rod (30½ square yards), and should be lightly stirred in with a hoe if the weather be dry. Showery weather is, however, the best time to apply scot and other surface dressings. The advertised manures are good, but in applying these

and guano they must be kept from the foliage, and especially the centre of the plants. Two pounds per rod of any of these is a sufficient dressing, and should be given as a first dressing in May, and may be repeated if mulching is not practised during the first moist weather in July.

Liquid manure may be applied advantageously through the summer. It should be poured between the rows, and if the ends of the rows are dammed up so as to be level with the ridges its passage into the soil will be insured with regularity. A good soaking should always be given and weak. It is difficult to state at what strength to apply the liquid from cesspools and tanks, but it is always better to apply it too weak than too strong. Ordinarily tanks that contain the drainings of stables, cow byres, and dung yards should be diluted with six times the bulk of water, or stronger material with twelve times the bulk of water, the liquid in all cases being well stirred and mixed. It is best given in a dull time that precedes rain after a period of bright weather or when, as the saying is, "It hangs for rain." A peck of soot and a peck of fresh cowdung put in separate bags in a tub, and 70 gallons of water added, poking the bags about two or three times a day for a week, will afford an excellent liquid manure. Feeding in liquid form will not be necessary in ordinary seasons after the middle of September.

**Removing Runners.**—The runners as they appear must be removed, and it should be done with a knife and with care so as not to break or damage the foliage, nor to loosen the plant's hold of the soil by dragging. The removal of the runners should be continued throughout the season. By this procedure the plants will form large well developed

in the least by keeping them in the dark frozen for weeks or months together. Protection may also be afforded by mats kept from the plants by stakes bent over them, and with the ends thrust in the ground so as to form hoops, and straw mats may be employed for a similar purpose. Evergreen branches, especially Spruce, are a good protection against frost. These materials should be used only when frosts prevail.

Before frost sets in clean the plantations, removing any decayed leaves, weeds, &c., and if the soil is very close point the surface over lightly and mulch shortly afterwards with an inch thickness of partially decayed litter, the rough being shaken out, or the remains of an old Mushroom bed. This will keep in the earth heat to some extent, and prevent the autumnal rains from washing the soil on to the flowers. Perhaps the best mulching of any for the winter season is straw somewhat coarsely chopped, and on heavy soils coarse ashes are serviceable, both being inimical to slugs through their sharp angles. It must be borne in mind that some Violets are tender, and liable to suffer in times of severe frost, especially when it prevails whilst the earth is bare. The Neapolitan in all its forms is not hardy, and it only becomes tenderer by high culture, so that if the ground is not covered with snow protection must be given. Straw hurdles or straw itself must be placed over the plants and remain during the severe weather. In early spring the Violets will push their flowers with genial weather, and whilst it is mild all will be well; but if a period of sharp weather, being what is popularly termed a black frost, succeed a spell of mild weather, we must be prepared to protect, or a few hours' frost, to say nothing of its being continued for days, may destroy

Fig. 87.—VANDA CRISTATA.

crowns, and the flowers will be fine or poor according to the treatment or growth of the preceding summer.

**Autumn and Winter Treatment.**—If varieties are grown that flower in autumn and through the winter in mild weather protection must be given. Frames are unquestionably the best, and of these span-roof are to be given preference. The frames should have low sides of wood not more than 10 inches to 12 inches in depth for the large growers, and 6 inches to 8 inches is sufficiently deep for the smaller growing sorts. A foot rise for the roof-lights of 9 inches from the sides to the centre is ample. All the lights must be hinged at the top, and so that they can not only be raised at the bottom for ventilation but turned over on to the other side of the frame, and the plants so exposed fully in mild weather and to allow of a thorough watering by rain or artificially if necessary, as well as to facilitate gathering the flowers. The frames should not be put on until frost, and from the day they are put on until they are taken off air must be given by tilting or raising the lights on both sides whenever the external temperature exceeds 35°, and when the temperature outside is 45° to 50° the lights should be turned over on opposite sides alternately. When the temperature is at those figures, and the atmosphere moist, or rain falls, the lights should be tilted or raised about 6 inches and on both sides. In severe weather give protection over the lights. Frigi domo, mats, straw mats, &c., are suitable. The protection should be removed daily when the nights only are frosty, but if the plants getting frozen through the night the protection must not be removed until they are thawed. In very severe weather the protection should remain on constantly after the plants are frozen until the general thaw, and if snow fall it should not be removed from the covering. The plants will not suffer

all the work of the previous season. To prevent such a calamity protection must be at hand. Nothing is better, failing frames, than Spruce branches stuck in the ground between the rows on the side from which the storm comes, and leaning from that side over the plants. It will mitigate the severity of the frost at night and of the parboiling effect of the sun by day. Protection of this character should always be held in readiness where Violets are cultivated, and when necessary be promptly and effectively applied.

The weather proving dry in spring, a good watering or waterings should be given between the rows, and always in the morning at this time of year, so as to allow the surface becoming fairly dry before night. Nothing short of high culture will grow high-class Violets, therefore supply liquid manure in spring if the plants show signs of exhaustion or enfeeblement in the blooms.

**Duration of the Plants.**—In order to obtain the fullest crop of the finest flowers, Violets must be treated as annuals; runners or suckers of the previous year's growth being planted in spring (or for special purposes rooted runners of the current year's growth may be planted in late summer and autumn, for which instructions will be given under the head of "Growing for Market"), and that time twelvemonth destroyed, or directly after flowering, and the securing of plants for new plantations. The plants will continue for many years, but they are never equal in freedom and size of flowers to the first season. If kept a second year, give a good dressing of manure after removing the large straggling foliage, and point it in. Keep free of weeds, mulch, water, and feed as in the first year, removing all runners, and the result will be a quantity of flowers, less in size, shorter in footstalk, yet of acceptable quality.

## SELECTIONS OF VIOLETS FOR OUTDOOR CULTURE.

I. Large growers for planting in rows 18 inches apart and 15 inches asunder in the rows. All have single flowers.

*Victoria Regina*.—Purple; the finest autumn, winter, and spring bloomer.

*Odoratissima*.—Blush violet, spring bloomer; the most floriferous, best shaped, and in every respect finest of its season.

*White Czar*.—White; the best of the single white Violets. Autumn, winter, and spring flowering.

II. Medium growers for planting in rows 15 inches apart, and 12 inches in the rows.

Single-flowered varieties:—

*Argenteaeflora*.—White tinted rosy purple; spring.

*Devoniensis*.—Purple; autumn and spring.

*Laviana*.—Lavender, white eye; spring.

Double-flowered varieties:—

*Rubra plena*.—Pink; spring.

*Queen of Violets* (Belle de Chatenay).—White, tinged purple; spring.

*Queen of Violets var. cœrulea*.—Light purple; spring.

III. Dwarf and close growers for planting in rows 12 inches apart and 9 inches asunder in the rows.

Single-flowered varieties:—

*Russian* (Scotch, London, floribunda, &c.).—Blue; spring.

*White Russian* (albiflora).—Spring.

*Rubra*.—Pink; spring.

Double varieties:—

*Double Scotch*.—Bluish purple; spring.

*Double White* (compacta).—Spring.

*Russian*.—Deep purple; spring.

*White Russian*.—Spring.

*Parmensis plena*.—Semi-double, white striped rose; spring.

*King of Violets*.—Indigo blue; spring.

*Patrie*.—Purple violet, slightly streaked red; autumn, winter, and spring.

The preceding are perfectly hardy; but the following are tender, yet when they survive the winter, as they do with protection as indicated before, they afford a quantity of flowers in spring, and some useful ones in autumn. Covered with frames they are best seen to advantage, flowered from September to April.

IV. Plant 15 inches asunder from row to row, and 12 inches apart in the rows.

*New York* (odorata pendula, Venice, Marguerite de Savoie, Count Brazza's Neapolitan, Marie Louise of some).—Deep mauve, streaked red, white eye.

*De Parme*.—Deep lavender, white eye.

*White Neapolitan* (Swanley White, Count Brazza's White Neapolitan).—Pure white, sometimes semi-double only.

## VIOLET FLORIBUNDA.

I AM obliged by Mr. Boothby's correction. Reference was not made to his variety, but the many synonyms of Russian, floribunda as generally grown being only a development of Russian by cultivation. Giant was also omitted, as it was only a magnified Russian, but I did not consider it could be put down as a synonym, being apparently a seedling development of Russian.

I omitted floribunda (Boothby) for the same reason as Prince Consort and Princess of Prussia, both Mr. G. Lee's raising—viz., because they were not, as far as I am aware, in commerce, and it is tantalising to readers to name varieties that cannot be had. Prince Consort and Princess of Prussia are the finest single Violets I have seen, and I hope to refer to them later on. Floribunda (Boothby), if I remember rightly, is very closely allied to Devoniensis, which probably originated from Giant, and Mr. Boothby has placed it beyond question that floribunda originated from Giant. This is very interesting and valuable information, as it shows Violets improve by cultivation, and seedlings of the highest cultivated forms are decided improvements on the parents, and goes to prove that much of the credit taken by hybridists is more due to cultivation and selection than anything else. I cannot determine the origin of Devoniensis. It is the first purple Violet with large blooms that flowers in autumn. If I remember rightly, Mr. Lee does not know its origin, and I only surmise it came from Giant, albeit the foliage is more after Wilsoni. This is a most curious flower—very narrow petals, white eye, and very sweetly scented. Devoniensis is very sweetly scented, and the foliage is more glaucous and pointed than in Giant, which certainly is the parent of Czar, and then we get White Czar, which has even more pointed foliage than Devoniensis and paler in colour, with a tendency to sparseness of reproduction; but this does not hold with White Czar, which is a great seeder. Czar has coriaceous foliage, so has Prince Consort. Victoria Regina, Odoratissima, and Princess of Prussia have pointed foliage, and much less hairy than either Czar or Prince Consort, so that we have two types, originating, as I think, from Russian or suavis, and I think the still less hairy, more glaucous, and more pointed foliage of Neapolitan to have originated from the same stock, being an albino form of suavis, the foliage bronzing under powerful sun. Single Neapolitan, if not white, is a pale lavender, white eye—due, I think, to the long cultivation of the Russian Violet in Italy and Greece, for the Violet is of great antiquity, being used as tiaras by belles at the Olympian games. Patrie I think pure Grecian, the oldest double Violet extant; anyway, I have had it from the Levant, and it is certainly of the Crimean type.

Having omitted Mr. Boothby's floribunda has caused its origin to be known. It is not the same as Russian, but intermediate between Giant

and Victoria Regina, about on a par as regards size of foliage and flowers with Devoniensis. I am glad to know it is an autumn bloomer, which I had not observed to be in advance in that respect of Devoniensis. If I remember rightly the flowers are bluish purple, fading to rosy purple, similar to Russian Superb.—VIOLEA.

## BATH AND WEST OF ENGLAND SOCIETY.

## HORTICULTURAL SECTION.—BRISTOL, JUNE, 2ND TO THE 7TH.

THIS always partakes more of the character of a loan Exhibition, the whole of the plants with the exception of a few Orchids being selected by the Steward of the section, the Hon. and Rev. J. T. Boscawen, from the collection of plants growing in the conservatories and houses of various gentlemen living principally in the neighbourhood of the Show. Further, the plants are grouped entirely under the supervision of Mr. Boscawen, and the consequence is, instead of the formal arrangements necessarily the rule at all flower shows, we have here a free artistic arrangement on the lines of a particularly well-furnished conservatory. A fine lofty tent with closed wooden ends painted a sombre black and not pleasing to all observers, who would have preferred ordinary canvas or canvas-draped ends, was devoted to the plants, and the two grand groups were very effective, creditable alike to growers, lenders, and the Steward. We cannot, however, speak very highly of the side benches, these not being so well filled as might have been expected.

The principal exhibitors of plants were F. Tagart, Esq., Old Sneed Park, Bristol (Mr. C. Miller, gardener), who had in different parts of the tent immense specimens of *Latania borbonica*, *Cycas revoluta*, *Arecas*, and other Palms, Crotons, a grandly flowered *Gardenia* and other plants. Very fine and imposing as arranged with flowering plants were the grand specimens of *Crotons interruptus*, *irregulare*, *Weismanni*, and *Challenger*, *Areca sapida*, *Latania borbonica*, *Cycas revoluta*, *Latania rubra*, *Cordylines*, and *Dracænas*. *Clerodendrons*, *Staphanotises*, and other plants lent by J. Derham, Esq., Sneyd Park, Bristol (Mr. W. Rye, gardener). Another important contribution was that by A. W. Summers, Esq. (Mr. A. Hancock, gardener), this including huge healthy specimens of *Latania borbonica* and *Cycas revoluta*, and good plants of *Areca lutescens*, *Cocos Weddelliana*, some capitally flowered trained plants of *Stephanotis floribunda* and other flowering plants and Ferns. Among the various plants sent by W. Pethick, Esq., Woodside, Stoke Bishop (Mr. E. S. Cole, gardener), the most noteworthy were a fine bank of *Gloxinias* interspersed with Maidenhair Ferns, several Orchids, as well as various flowering and fine-foliaged plants. W. E. George, Esq., Downside, Bristol (Mr. H. Young, gardener), also contributed numerous well-grown plants, including good examples of *Adiantum farleyense* and other Ferns, *Cordylines*, *Dracænas*, Palms, &c. In addition to several large and good Ferns the contribution from H. St. Vincent-Ames, Esq., Cote House, Westbury-on-Trym (Mr. W. Bannister, gardener), included several very fine well-flowered *Marguerites*, and which are still surprisingly popular. H. Mardon, Esq. (gardener, J. Stapleton) also sent a considerable number of flowering and fine-foliaged plants all in a healthy condition, and we believe there were a few other contributors whose names we were unable to procure. The principal contribution by Mrs. Miller, Brentry House, Westbury-on-Trym (gardener, F. Nicholl), were four well-fruited pot Vines. The varieties were Black Hamburgh and Foster's S-edling, and as trained over arches at the end of the tent in connection with other fruit trees which we have yet to notice, the effect was very pleasing.

Prizes were offered for a bank of Orchids and also for a single specimen, but these failed to attract more than one competitor—viz., H. Cruger Mills, Esq., Penpole, Shirehampton (gardener, Mr. F. Perry), who was awarded the first prize of £10 for an attractive group, which comprised *Lælia purpurata*, *Cattleya Mendeli*, *Odontoglossum Pearcei*, *Aerides*, *Cypripediums*, and other kinds in good condition. E. Saunderson, Esq., Clifton (Mr. Phillips, gardener), also contributed a small bank of choice Orchids, but not for competition.

Of the trade growers represented the principal exhibitors were the Messrs. R. Smith & Co., Worcester, this well-known firm greatly beautifying the tent with Clematises, Rhododendrons, and other hardy flowering shrubs. The large trained plants of the former interspersed among the various fine-foliaged and flowering plants above noticed were singularly attractive, and many were the inquiries concerning the small well-flowered plants grouped in baskets. Some of the best of the Clematises were Anderson Henry, Fairy Queen, Gloire de St. Julien, Lady Caroline Nevill, Marie Lefevre, Princess of Wales, Sensation, these belonging to the lanuginosa section; Barillet Deschamps, Countess of Lovelace, Enchantress, and Venus Victrix, Florida section; and Miss Bateman a representative of the patens section. Some of the best of the Rhododendrons were Purity, Lady Rolle, Lady C. Neville, Mrs. J. Clifton, Everestianum, Mrs. T. Sebright, Duchess of Sutherland, Pouissin, Old Port, and Mrs. Fitzgerald. Mr. Charles Turner, Slough, sent a fine group of specimen Pelargoniums, all fresh and well flowered; and of these the best were Decorator, Rosetta, Dicky Grand, Duchesse de Morny, Madame C. Koling (charming, pure white), Mrs. Ashby, Maid of Honour, Countess de Choisseuil, Gold Mine, Miss Ashby, Triomphe de St. Mandé, Empress of Russia, Mons. Desmoulin, Lady of the Lake, Garibaldi, Rosy Morn, Duchess of Bedford, and Prince of Wales, altogether a good selection. From Messrs. J. Laing & Co., Stanstead Park Nurseries, London, came a fine assortment of plants and cut blooms of Tuberous-rooted Begonias, a speciality for which this firm has deservedly become noted. Of the single varieties the following may be said to be a good and well varied selection:—Rose Perfection, Guardsman, Sunrise, Count of Roslyn, Mrs. Welles, Princess of Wales, Lady Falmouth, Sir P. Lumsden, Prince of Wales (very fine), Primrose Queen, Blushing Bride, Charmers, and New Colour. The doubles were not so well developed, but Alba plena, Marquis of Bristol, Earl of Beaconsfield, Le Grande Citoyen, Marchioness of Stafford, and Prince Albert Victor were noteworthy. Messrs. Pearson, Chilwell Nurseries, Nottingham, exhibited three large stands of cut blooms of Zonal Pelargoniums, and these again were much admired. This class of plants have long been a speciality at Chilwell, the late Mr. Pearson having raised numerous very fine sorts, and his son still continues the improvement so worthily commenced. In addition to

several very superior unnamed seedlings they had such of their varieties as best represented each shade of colour. Of these the most noteworthy were *Aspasia*, Mrs. Gordon, Mrs. H. T. Barker, Norah, Mrs. Miller, Lady Chesterfield, Nelly Thomas, Viola, M. Myriel, and Mrs. Holford, all remarkable alike for the size and form of truss and individual pips. Mr. F. Hooper, Bath, had a long array of stands of Pansies, each section being strongly represented. Near these Mr. Turner had a stand of Carnations, which, owing to their great size, good form, and bright colours, surprised nearly all that saw them, such blooms not often being seen in the West of England.

At the end of tent opposite the entrance Messrs. J. Cheal & Sons, Crawley, Sussex, had a very interesting and instructive exhibit of cordon-trained fruit trees. Some were trained over an archway intended to span a garden work, others were trained diamond-shape to a wire fencing, and besides these there were single, horizontal, vertical, and obliquely trained trees, principally of Apples and Pears, and all well set with fruit. Mr. Cheal also on the second day of the Show gave a lecture on the subject of cordon-trained fruit trees, and doubtless convinced many of his hearers that the system has much to commend it. Those especially who desire a quick return for their outlay, or who only require a limited quantity of extra fine fruit, should give this system a good trial. Messrs. Cheal also had a well-kept collection of Apples, of which the best were Herefordshire Pearmain, Marfitt's Seedling, Dutch Mignonne, Hornead's Pearmain, Scarlet Nonpareil, Welford Park Nonesuch, Claygate Pearmain, Norfolk Beefing, French Crah, Annie Elizabeth, and Bess Pool. Near these was a very handsome dish of Tomato Hathaway's Excelsior, contributed by Mr. W. Bannister, and also the dishes of Strawberries, six in all, staged in competition for the valuable prizes offered for them. The first prize was awarded to J. Lysaght, Esq. (F. Edwards, gardener), for a handsome dish of Alice Maud, but which more resembled James Veitch. Mr. E. Miller was second with a good dish of President, and Mr. E. S. Cole third with La Grosse Sucrée of good size and colour.

**HORTICULTURAL STRUCTURES.**—Several well-known firms had extensive exhibits, conspicuous among these being the serviceable, strongly built, yet elegant conservatories, fruit houses, and frames, erected by Messrs. Foster and Pearson, Beeston, Notts. Their system of ventilating the improved frames and movable span-roofed forcing pits is especially to be commended, and the amateurs' greenhouse or conservatory is among the best of its kind. They also had several boilers on view, as well as fittings for houses, valves and joints for pipes, all denoted superior workmanship. Messrs. Deane and Co., of King William Street, London Bridge, had good examples of small conservatories, amateurs' greenhouses, forcing houses, and frames of a character to meet the requirements of all classes of horticulturists, and they also had boilers and other appliances necessary to gardeners. Messrs. Richardson & Co., horticultural builders, Darlington, exhibited several useful structures well adapted for all who may need houses, whether for plant or fruit growing, some being ventilated on their patent system, and others with the ordinary systems. Their wall copings, Peach cases, detached span-roofed forcing or plant houses, were all good examples of modern styles, and the Parisian greenhouse blinds came in for a good share of attention. These appear to be of a very durable character, but afford rather too much shade for many subjects.

Another noteworthy series of exhibits were the "patent Venetian" flower and fruit houses erected by Messrs. Skinner & Board, Stokes Croft, Bristol. These are specially to be commended for fruit houses, as they are so constructed as to admit of the several laps composing the roof covering to be easily opened at any angle, thereby admitting little or much air all over the roof, or they can be so adjusted as to allow the whole of the rainfall to reach the trees and borders—an obvious advantage. This firm also had examples of revolving wall copings, of tubular boilers, and other appliances. Messrs. Wright & Holmes, Mosely Road, Birmingham, also had several useful houses, some being designed specially for amateurs, all being well constructed and ventilated on good principles. Mr. W. Parham, Northgate Works, Bath, had a conspicuous exhibit, their houses of all descriptions, as well as wall coping, Peach cases, and frames being glazed on Cranston's patent system of glazing, of which he is now the sole proprietor. Mr. Wood, Eastville, Bristol, has his gold medal boilers working satisfactorily; he also exhibited his patent kitchen range boiler, tenants' greenhouses, and other articles.

Mowing machines and various implements connected with horticulture were largely exhibited in different parts of the grounds, but we must conclude this notice with a few merited remarks upon the extensive exhibit of pottery by Mr. John Matthews, The Royal Pottery, Weston-super-Mare. This included a wonderful variety of ornamental vases, large and small, fountains, statuary, and every kind of pot, pan, saucer, hanging baskets, brackets, tiles, &c., that are now in demand by horticulturists and others. Many of them are elegant in design, all are well made, and calculated to be most durable and serviceable. Near these were arranged in a somewhat similar style and furnished with plants as in Mr. Matthews's case, were a number of vases, pots, &c., made and sold by Mr. C. Warne, Weston-super-Mare, and these also appeared to be well made. We had nearly omitted mention of the tree guards shown round strong park trees furnished by Messrs. Garaway & Co., Durham Downs Nursery, Clifton, these being portable, lightly constructed, therefore cheap, yet give promise of being very durable and well adapted for the purpose for which they are made. They are called "Cole's Patent Invincible" and are the invention of Mr. G. S. Cole, The Dean, Gloucester. Messrs. Garaway also furnished a considerable number of plants for the decoration of some of the structures in which various processes were illustrated at different times. The exhibits of the leading seedsmen and others are commented upon in another part of this Journal.

#### ODONTOGLOSSUM VEXILLARIUM.

HEREWITH I send you two racemes of *Odontoglossum vexillarium*, and I think you will admit they are very fine, especially the one with the lateral, which is unusual. One spike you will observe bears ten flowers and the other nine. We have at present a very fine display of this Orchid—about sixty plants in bloom in grand condition. These we have grown from small single imported pieces during the last four years, and we have

not a poor variety amongst them. I find they do best by being kept gently growing nearly all the year round, and I think you will see by the samples sent that such treatment suits them.—J. RIDOUT, *Gardener to T. B. Haywood, Esq., Woodhatch Lodge, Reigate.*

[Unquestionably the treatment has suited them. The flowers are very fine indeed, some of them exceeding  $4\frac{1}{2}$  inches in length and  $3\frac{1}{2}$  inches across the labellum; they are stout in texture, good in colour, and very handsome.]

#### ROYAL HORTICULTURAL SOCIETY.

JUNE 8TH.

THE Exhibition on this occasion was devoted to Orchids, and though only six classes were allotted to them, a pretty display was produced by the collections entered in competition. There were also extensive groups of Pæonies, Irises, and hardy flowers generally that furnished considerable attractions to the visitors.

**THE ORCHIDS.**—The competition was not quite so keen as might have been expected, being restricted to five exhibitors, but the specimens were well flowered, although some of the largest were notable examples of the "made-up type," three or four varieties being observable in one pot. In the nurserymen's class for twelve Orchids Mr. J. Cypher, Queen's Road, Cheltenham, was first with large specimens, and mostly flowering profusely. The best of those represented were *Lælia purpurata*, with four spikes or twenty flowers; *Cattleya Mendeli grandiflora*, a fine variety with three large flowers; *Odontoglossum vexillarium*, seventeen flowers; *Anguloa Clowesi*, a magnificent specimen, thirteen fine flowers; *Vanda suavis*, three racemes; *Cattleya Mossiae*, a huge mass 3 feet in diameter and crowded with flowers; *Epidendrum vitellinum*, of similar size, with over fifty racemes; *Cypripedium Lawrencianum*, handsome; *Dendrobium thyrsiflorum*, twenty-four racemes; *Cattleya Mendeli* and *C. Mossiae grandis*. The second prize was awarded to Mr. H. James, Castle Nursery, Lower Norwood, for a neat collection, of which the best plants were *Aerides Lobbi grandis*, a very fine variety, the flowers richly coloured; *Odontoglossum vexillarium*, *Masdevallia Harryana*, *Dendrobium Bensoniae*, and *Calanthe veratifolia*, all beautifully flowered. In the amateurs' class for the same number of Orchids Mr. C. J. Salter, gardener to J. Southgate, Esq., Selborne, Stratham, was awarded first honours, showing a very handsome collection of vigorous plants. An extremely pretty variety of *Odontoglossum vexillarium* named *picturatum*, with white lips and rosy sepals and petals, had eight fine racemes; *Dendrobium suavisimum*, twelve racemes of its golden flowers; *Cattleya Warneri* was attractive, *C. gigas* had eleven large richly coloured flowers, *Aerides Fieldingi* was very beautiful with four panicles of flowers, *Cattleya Wagneri* was very noticeable, pure white with the lip golden in the throat; *Oncidium macranthum* was represented by a fine variety; *Odontoglossum vexillarium*, *Anguloa Ruckeri*, and *Cypripedium Lawrencianum*, with twenty-four flowers, were also notable specimens. Mr. F. J. Hill, gardener to H. Little, Esq., The Barrons, Twickenham, secured the second place, one of his best plants being *Cattleya intricata*, a supposed hybrid between *Cattleya amethystina* and *Lælia elegans*. *C. Mendeli*, *C. Mossiae*, *Odontoglossum Pescatorei*, and *Cypripedium niveum*, were also well shown.

Classes for six Orchids were also provided for amateurs and nurserymen; amongst the former Mr. Cooke, gardener to De B. Crawshaw, Esq., Rosefield, Sevenoaks, took the lead with plants of medium size, but fresh and healthy, of *Vanda suavis*, *Cattleya Warneri*, *Epidendrum vitellinum majus*, *Odontoglossum vexillarium*, and *Cattleya Mendeli*. Mr. C. J. Salter followed closely, *Maxillaria Turneri* being well flowered; also several *Cattleyas*. Messrs. Cypher and James were respectively first and second in the nurserymen's class for six, both showing good plants, but the former had the largest and most freely flowered specimens.

The only group of *Odontoglossums* was from Mr. H. James, who was awarded the first prize for an extremely pretty collection of plants arranged with Ferns. Numerous varieties of crispum were shown with *polyxanthum*, *Pescatorei*, *sculptum*, *Andersonianum*, *citrosum*, *vexillarium roseum*, *Willekanum*, *cordatum Kirnastianum*, a very dark coloured variety; *Lehmanni*, a pretty variety, white-edged with rose; *cordatum aureum* and *niveum majus*. The competition was closer with six *Cattleyas* or *Lælias*, four exhibitors entering. Mr. J. Cypher was again first, his plants comprising *Lælia purpurata alba*, with nine flowers; *L. purpurata Brysiana*, with twenty-one flowers; *Cattleya Mossiae grandis*, *C. Mendeli grandiflora*, *C. Mossiae*, and *C. lohata*, with five good flowers, the lip handsomely veined with deep crimson. Mr. Cooke followed, his best plants being *Lælia purpurata* and the light variety *Russelliana*. Mr. H. James was third, his best specimen being a very fine variety of *C. gigas*.

**Miscellaneous Groups.**—Silver-gilt medals were awarded to the three following exhibitors for collections of cut flowers. Messrs. Kelway & Son, Langport, Somerset, had a great number of Pæonies, Pyrethrums, single and double, extremely bright and varied, Irises, representing all the types now flowering, and miscellaneous hardy flowers. Mr. T. S. Ware, Halo Farm, Tottenham, contributed an imposing group of outdoor flowers, his collection of herbaceous and other Pæonies being exceedingly beautiful; Irises, the early dwarf *Papaver bracteatum præcox*, the yellow Day Lily, *Hemerocallis flava*, the white-lipped *Cypripedium occidentale*, and *Anthriscum liliatum*, also formed interesting features. Messrs. Barr & Son, Covent Garden, had a similarly attractive group of Pyrethrums, Irises, and other flowers. Bronze medals were awarded to Messrs. W. Paul & Son, Waltham Cross, for a large collection of Rhododendron flowers, representing a great number of Choice varieties, together with baskets of "Scotch Roses," and the charming bright copper Austrian Rose, which attracted much attention owing to its bright colour; and to Messrs. Hugh Low & Co., Clapton, for groups of *Odontoglossum crispum* and *Cattleya Mossiae* varieties, comprising some very handsome forms of both species. Messrs. Hooper & Co., Covent Garden, had an interesting group of Ivy-leaved Pelargoniums and double Pæonies. Messrs. E. H. Krelage & Son, Haarlem, Holland, showed a collection of Irises varieties of *germanica*, *equidens*, *pallida*, *siberica*, and others, and groups of well-grown *Fuchsias*, and *Saxifraga nepalensis* were contributed from the Society's Gardens at Chiswick.

**FRUIT COMMITTEE.**—Present: T. Francis Rivers, Esq., in the chair, and Messrs. G. T. Miles, G. Norman, J. Burnett, John E. Lane, John Woodbridge, William Warren, William Denning, T. B. Haywood, and Harry J. Veitch.

Messrs. Thomas Rivers & Son, Sawbridgeworth, were awarded a cultural commendation for fruits of Early Favourite Plum, a small round dark variety of excellent flavour. A vote of thanks was also awarded for well-kept Dumelow's Seedling Apples. Mr. Lockie, Oakley Court Gardens, Windsor, showed a green-fleshed Melon named Oakley Court Seedling, a cross between Dr. Hogg and Egyptian Greenflesh. It was scarcely ripe, and the Committee desired to see it again. Mr. E. S. Wiles, Elgcote Park, Banbury, exhibited a Melon named Elgcote Beauty, a cross between Captain Larks and Golden Perfection, but it was passed.

The South Australian Commissioners showed some ripe and finely flavoured Winter Nelis Pears, Potatoes something like a rough Vicar of Laleham, Onions, and dried or preserved fruits, comprising Pears, Peaches, and Plums, for which votes of thanks were accorded. It was stated that the Potatoes were at the disposal of the Committee for distribution, subject to the results being made known to Sir Samuel Davenport, Commissioner for South Australia.

Mr. March, Board of Green Cloth, Buckingham Palace, exhibited some frames to illustrate his method of "water protection for plants." They were ordinary box frames with a flat glass top, but with wooden sides to form a kind of trough in which water was to be placed, that, when frozen, it is thought, would protect the plants below. It was referred to Chiswick for trial.

**FLORAL COMMITTEE.**—Present Mr. James O'Brien in the chair, and Messrs. Harry Turner, A. J. Lendy, H. M. Pollett, Amos Perry, G. Paul, Shirley Hibberd, H. Herbst, W. Wilks, W. H. Lowe, W. Bealby, H. Cannell, W. B. Kellock, E. Hill, William Holmes, and J. Dominy.

Mr. W. Stacey, Dunmow, had a stand of two dozen Verbena trusses, representing some of the handsome varieties that he has raised in recent years, and which are remarkable for their bright clear colours and size of flower and truss, being especially valuable for culture in pots where others of a sturdy character are adapted for bedding out. Very notable were Alba Magna, pure white; Acquisition, a distinct rosy salmon tint, extremely bright; Purity, white; Purple Queen, rich purple; Lord Charles Beresford, dark scarlet; Fairy Queen, striped; Cantab, large light purplish-blue; Lilacina, lilac; and Lady C. Beresford, scarlet which was certificated. F. G. Tautz, Esq., Goldhawk Road, Hammersmith, exhibited several fine semi-double Tree Pæonies, two of which were certificated. Mr. G. Burnett, The Grange, Hillingdon, showed two seedling varieties of Decorative Pelargoniums named Miss Dyson, rosy salmon and dark blotch, and Beauty of Hillingdon, pale rose. Both are very free, and a vote of thanks was accorded for them. C. Dorman, Esq., The Firs, Lawrie Park, Sydenham (gardener, Mr. W. White), had several choice Orchids, one of the most notable being *Maxillaria Sanderiana*, with large white flowers stained with claret at the base of the sepals and petals; *Odontoglossum crispum* Mrs. C. Dorman was a distinct variety, the sepals and petals margined with rosy crimson on a white ground; *Oncidium pulchellum*, a graceful species with light panicles of small blush white flowers; *Epidendrum vitellinum* maximum, very large and bright; *Cattleya Wagneri*, white with gold throat; *Odontoglossum Andersonianum*, variety Dorman, delicate buff, with brown spots; and *Cattleya Reineckiana*, with white sepals and petals, the lip veined with crimson (vote of thanks). Mr. Cypher had a pale rose-lipped *Lælia purpurata* named *pallida rosea* and some distinct varieties of *Cattleya Mossiae* and *Mendeli*. G. Nevill Wyatt, Esq., Lake House, Cheltenham, showed a pile variety of *Cattleya Mossiae*, named *Wyattiana*. H. M. Pollett, Esq., Fernside, Bickley, showed *Cypripedium Godfreyæ argenteum*, a variety with silvery leaves. S. Courtauld, Esq., Bocking Place, Braintree (gardener Mr. A. Wright), was awarded a cultural commendation for a plant of *Masdevallia rosea* in a 48-size pot, with about 120 flowers, the best example of this floriferous species that we have seen. The New Plant and Bulb Company had two pretty varieties of *Cattleya Mossiae*. Walter Cobb, Esq., Silverdale, Sydenham, showed a fine pure white variety of *Odontoglossum crispum* (vote of thanks). Mr. J. King, Rowsham, had a new *Coleus* named *Vesuvius*, with large leaves, very bright red, neatly edged with gold, an effective variety. Mr. R. Underwood, Fortune Green, Kilburn, showed a *Pelargonium*, sport with scarlet and blush flowers on the same plant (vote of thanks). Messrs. J. Laing & Co. sent a beautiful double Tuberous Begonia named *Triumph*, with very full blooms of a rich salmon hue. Messrs. H. Cannell & Sons, Swanley, had a small collection of choice new *Gloxinia*s, one of which—*Ormonde*—was certificated. The best of the others were *Snowdrift*, white; *Viceroy*, crimson, white throat; and Mrs. Amherst-Morris, purple, dotted with crimson.

A series of water-colour sketches of Orchids, faithful and well executed representations of plants in Mr. A. H. Smee's collection, the work of A. Foord Hughes, Esq., Wandle Bank, Wallington, was exhibited and greatly admired by many visitors. *Oncidium Jonesianum*, *Vanda Sanderiana*, and *Odontoglossum crispum* were especially well depicted, *Zygopetalums*, *Cattleyas*, and other plants being carefully and correctly drawn. Messrs. Jones and Firmin, 120, Blackfriars Road, showed a mirror, upon the back of which a plant of *Odontoglossum crispum* with a fine raceme of flowers had been painted previous to the glass being silvered. It had a pleasing effect and was tastefully sketched. Mr. H. G. Smyth, Goldsmith Street, Drury Lane, exhibited a very good example of *Orchid* peat.

M. M. Vervaeke & Cie, Ghent, Belgium, showed a plant of *Odontoglossum Vuylstikianum*, which was something like a yellow *O. luteo-purpureum*, the sepals and petals undulated and the lip fringed.

#### CERTIFICATED PLANTS.

*Verbena Lady C. Beresford* (Stacey).—A bright rosy scarlet variety, with a white eye; very effective and handsome.

*Pæonia Moutan lilacina* (F. G. Tautz).—A large semi-double variety, white stained with purple at the base. *Purity*, similar in shape and style, but pure white.

*Cattleya speciosissima*, *Fairfax* variety (Admiral Fairfax, Ravenswood, Melrose, N.B.).—Very handsome, with broad crimson petals, narrow sepals of similar colour, and a large round dark crimson lip.

*Gloxinia Ormonde* (H. Cannell & Sons).—An exceedingly dark crimson variety of very rich colour.

*Pyrethrum roseum Ormonde* (Kelway & Son).—A double variety of a bright rose tint, close cut florets, very full.

*Pyrethrum roseum*, *Princess of Wales* (Kelway & Son).—A single variety, bright rose, very large, and of good form.

*Pyrethrum Mrs. Bateman Brown* (T. S. Ware).—Single, rich rose-crimson, very fine colour and excellent shape.

*Iris Victorine* (Kelway & Son).—A pretty variety of the germanica type, with dark blue falls and white standards veined with purple.

*Pæony Eclair* (Kelway & Son).—One of the herbaceous Pæonies, with pinkish white double flowers; very full and handsome.

*Pæony Festiva maxima* (T. S. Ware).—An herbaceous variety, with large double white blooms, slightly tinged with red, very fragrant.

**SCIENTIFIC COMMITTEE.**—A. Grote, Esq., in the chair.

*Red-spotted Potatoes.*—Dr. Masters observed with reference to Mr. Plowright's communication made to the last meeting, that although many were found in the experiments at Chiswick in 1884, none whatever occurred in 1885.

*Apples and Pears attacked by Erysiphe Communis.*—Mr. W. G. Smith stated that the trees at Dunstable were badly attacked this year by an "oidium." It had often been noticed before, but it had not previously been identified with *E. communis*. It attacks the stamens and pistil, destroying the pollen.

*Circea Lutetiana* with *Stipules.*—Dr. Masters brought plants, and called attention to the fact, previously unobserved, that this species possessed minute gland-like stipules, which disappeared from the older and lower portion of the plants.

*Hawthorn Shoot from Root.*—He also exhibited a shoot of *Crataegus Pyracantha* springing from a root.

*Deutzia gracilis* with "blind flowers."—Dr. Lowe brought specimens showing that these produced no fruit, but often bore isolated flowers with perfect organs.

*Senecio spathulifolia.*—He also exhibited fine specimens of this plant growing in the open. It is a native of Holyhead, and said to be in Yorkshire by Backhouse. Mr. Boscawen observed that the Groundsels are all best raised from green seed, which come up quicker and better than when dried. It is the same with Lilies. Dr. Lowe also exhibited plants of *Aster aurantius*, originally received from the late Mr. Joad.

*Potato with Phycomyces nitens.*—A specimen was received from Mr. Wills with the silky-looking fungus, which appeared to be in fructification. It was referred to Mr. Smith for further examination and report.

*Ascomyces Alni.*—A specimen of Alder root covered with excrescences due to this fungus was sent by Mr. Bunyard of Maidstone.

*Anthericum Liliastrium* and *Delphinium.*—He also sent isolated blossoms of these plants springing from the base of the plants in anticipation of the usual spikes.

*Method of Lighting with the Interposition of Water.*—Mr. T. C. March (of the Board of Green Cloth, Buckingham Palace) was invited to give some account of his invention, which consists of introducing a shallow glass tank over the plants. This stops the heat rays but allows the light to penetrate freely. Mr. Stirling, the Queen's gardener, is experimenting with it, and finds *Fuchsias*, *Ferns*, &c., grow extremely well under it. It was suggested that it might be useful to adopt some form of the arrangement in tropical countries with advantage.

#### REVIEW OF BOOK.

*Flowers, Fruits, and Leaves.* By Sir JOHN LUBBOCK, Bart., F.R.S., M.P., D.C.L., LL.D. London: Macmillan and Co. 1886.

WE have already a number of works from Sir John Lubbock's prolific pen, several of which have taken a high place amongst popular scientific treatises, but to many persons the work now under notice will probably prove one of the most interesting. The author has repeatedly given good evidence of his acute and accurate observations in natural history, and it might be well imagined that bringing this attentive study to bear upon plant peculiarities, something original and instructive would result. With regard to one portion of the subject, however, that relating to the cross-fertilisation of flowers, so much has appeared in late years, that little room has been left for original investigation, but a comparison of the recorded observations is very useful, especially as the author has himself paid special attention to the matter, as related in his "Flowers and Insects," published some ten years since. Upon the structure of fruits and seeds treated popularly there has been less of an authoritative character, while the chapters on leaves, which conclude the work, contain much that will be new to many readers.

We may briefly note the features of these divisions. In chapter i., dealing with flowers, cross-fertilisation, specialisation of structure to encourage insect visits, and the observations on insectivorous plants are reviewed. Mr. C. Darwin's experiments also receive consideration, as well as those of other celebrated European naturalists. The structure of *Geranium pratense* is described and illustrated, also *Epilobium angustifolium* and *Vallisneria spiralis*, but a much fuller description of the latter, with an illustration, is given in chapter iii., page 51, though there is apparently a slight inconsistency in the two references. At page 10, it is said, after describing the female flowers, that "the male flowers are minute and sessile, but when mature they detach themselves from the plant, rise to the surface, and float about freely like little boats among the female flowers." On page 51, however, it is said that "the male flowers have short straight stalks, from which, when mature, the pollen detaches itself, rises to the surface, and floating freely on it, is waited about so that it comes in contact with the female flowers." The italicised word indicates the seeming discrepancy.

Some space is devoted to the consideration of the author's favourite study, the partiality of bees for particular colours. He says, "In order

to test the power of bees to appreciate colour, I placed some honey on a slip of glass, and put the glass on coloured paper. For instance, I put some honey in this manner on a piece of blue paper, and when a bee had made several journeys, and thus become accustomed to the blue colour, I placed some more honey in the same manner on orange paper about a foot away. Then during one of the absences of the bee I transposed the two colours, leaving the honey itself in the same place as before. The bee returned as usual to the place where she had been accustomed to find the honey; but though it was still there, she did not alight, but paused for a moment, and then dashed straight away to the blue paper. No one who saw my bee at that moment could have had the slightest doubt of her power of distinguishing blue from orange."

The structure of several common flowers is explained, and the subject is continued on chapter ii., which also deals with "cleistogamous flowers," "dimorphism," "the purpose of honey," "the protection of plants," "the sleep of plants," "the scent of flowers," and concludes with the "origin of flowers," from which we extract the following remarks. "Nevertheless although flowers present us with these beautiful and complex contrivances, whereby the transfer of pollen from flower to flower is provided for, and waste is prevented, yet they appear to be imperfect, or at least not yet perfect in their adaptations. Many small insects obtain access to flowers and rob them of their contents. *Malva rotundifolia* can be, and often is, sucked by bees from the outside, in which case the flower derives no advantage from the visit of the insect. In *Medicago sativa*, also, insects

Fig. 88.—*Odontoglossum crispum* Cooksoni.

can suck the honey without effecting fertilisation, and the same flower continues to secrete honey after fertilisation has taken place, and when, apparently, it can no longer be of any use. Fritz Müller has observed that though *Posoqueria fragrans* is exclusively fertilised by night-flying insects, many of the flowers open in the day, and consequently remain sterile. It is of course possible that these cases may be explained away; nevertheless, as both insects and flowers are continually altering in their structure, and in their geographical distribution, we should naturally expect to find such instances. Water continually tends to find its own level; animals and plants as constantly tend to adapt themselves to their conditions. For it is obvious that any blossom which differed from the form and size best adapted to secure the due transference of the pollen would be less likely to be fertilised than others; while on the other hand, those richest in honey, sweetest, and most conspicuous, would most surely attract the attention and secure the visits of insects; and thus, just as our gardeners, by selecting seed from the most beautiful varieties, have done so much to adorn our gardens, so have insects, by fertilising the largest and most brilliant flowers, contributed unconsciously, but not less effectually, to the beauty of our woods and fields."

Two chapters of fifty-two pages are devoted to fruits and seeds, respecting which much varied information is given. The forms of fruits and seeds are considered, and the various methods by which the latter are distributed. Referring to the protection of seeds, it is observed that this is "in many cases attained by curious movement of the plant itself," and the Sensitive Plant, *Averrhoa Bilimbi* and *Desmodium gyrans* are described. As in all these cases the movements are those of the leaves, it might be thought that their consideration would have been better in the

chapter devoted to them, but that is of little moment. In describing the *Desmodium*, it is said that "the leaflets are perpetually moving round and round," an expression which will not convey a clear idea of their motion to a person unacquainted with the plant. The small leaflets are situated on each side, at the base of the central larger lobe, and they rise alternately by jerks until vertical, and then descend again.

In the chapters on leaves, the leading points discussed are the differences of forms and structure, particulars of extremely interesting experiments being incorporated. Numerous illustrations are given, and the work, which is neatly bound in cloth, will be valued by all who are interested in plant structure.

#### GARDENERS AND PREMIUMS.

ON page 439, "*Lathyrus*" is, to my thinking, far below the average in his estimate when he says "it is very questionable if the term apprentice applies to 5 per cent. of gardeners." If young beginners in gardens are not termed apprentices I should like to know what they are termed; but as far as my experience goes, I have generally heard them termed apprentices, even if no premium has been paid, and it is a certainty that no young gardener is termed a journeyman until he has served two or three years' apprenticeship; therefore I think "*Lathyrus*" might safely say, without exaggeration, 50 per cent. instead of 5. But I will admit that, as a rule, there is no legal tie made when a premium is paid in our profession; but there are exceptions to every rule, for I could point out to "*Lathyrus*" more cases than one where indentures were drawn up and signed by a lawyer when premiums were paid. Again, "*Lathyrus*" says, "It is not youths that are first entering gardens who pay premiums, but young men that have already served some years," but I have not found it the case. In the place stated at page 417 no premium was demanded from young men that were termed journeymen, but merely from beginners, or from youths that had served one or two years in a second-rate garden, and at the same time fairly good wages were paid to the apprentices according to their abilities. Therefore I cannot agree with your correspondent in saying that where premiums are received they are paid the lowest wages; but I have known places where no premium was required, but very low wages paid in lieu of premiums, so in the end it amounts to the same thing. Again "*Lathyrus*" seems anxious to know where I see "the resemblance between gardening and any other trade." I will admit that gardening is not generally termed a trade, therefore had I known that "*Lathyrus*" had been such a critic I would not have used the word, but at the same time there are other callings beside gardening that can scarcely be termed trades where beginners have to pay a premium or work for very low wages, and, in fact, in some cases, receive no wages for the first year.—AN OUTSIDE FOREMAN.

#### ODONTOGLOSSUM CRISPUM COOKSONI.

NUMEROUS handsome varieties of *Odontoglossum crispum* have been introduced, and there are now all gradations from the pure white spotless forms that are usually termed *O. Alexandrae*, to the heavily spotted varieties either on a white, a yellow, or a rosy ground. One of the finest of the spotted type is *O. crispum* Cooksoni, which is named in honour of a distinguished Orchid amateur, N. C. Cookson, Esq., Wylam-on-Tyne. It was introduced from New Grenada, and is remarkable alike for the size of the flowers and the richly coloured large spots. The sepals and petals are pure white, and upon this the dark reddish-brown blotches show up very boldly. Our figure represents a single flower the natural size, and a faithful coloured plate was given in "*Williams's Orchid Album*," vol. iii., t. 118. As in the case of all such varieties, this must continue scarce and valuable for a long time to come, but it forms a good example of the best of the spotted varieties in contrast with the White *O. crispum* which we have previously figured.

#### ROYAL BOTANIC SOCIETY.

JUNE 9TH.

THE second summer Show of this Society is always one of the leading horticultural events of the London season, and on this occasion it was no exception to the rule, for the entries were numerous, of excellent quality, and were arranged in Mr. Coomber's usual tasteful manner. The principal attractions were the Orchids, which formed magnificent banks. The stove and greenhouse plants and the Pelargoniums were also notable, together with the miscellaneous groups from the nurserymen, which invariably constitute such an important portion of these exhibitions. Cut flowers were also numerous represented, but fruit was shown by few, owing to the season being very late with indoor productions as well as those from outdoors. Some of the exhibits were good, however, especially the Peaches and Nectarines.

ORCHIDS.—Some grand specimens were included in the classes devoted to these, one of the most remarkable being Mr. Douglas's *Odontoglossum vexillarium*, which had forty-seven racemes, or a total of 289 flowers. This was shown in the class for twelve specimens, and was much the finest plant exhibited. Five classes were provided, each for twelve Orchids, the first two for exotic species, or varieties from nurserymen and amateurs, the second two for single specimens divided in the same way, and the third for twelve European Orchids, in which there was no entry. The successful amateur exhibitors were Mr. J. Douglas, gardener to Francis Whitbourn, Esq., Great Gearies, Ilford, who was first both with the single specimen and

twelve other specimens. The second prize for single specimens was gained by Mr. S. Cooke, gardener to De B. Crawshaw, Esq., Rosefield, Sevenoaks; and the third by Mr. W. May, gardener to F. C. Jacob, Esq., Amhurst Park, Stamford Hill. In the other amateurs' class Mr. J. Douglas was followed by Mr. C. J. Salter, gardener to J. Southgate, Esq., Selborne, Streatham, and Mr. F. J. Hill, gardener to H. Little, Esq., The Barrons, Twickenham, who had similar plants to those at South Kensington on the previous day. The best twelve single specimens from nurserymen were shown by Mr. J. Cypher, and followed by Mr. H. James and Messrs. Jackson & Sons, Kingston. In the other class for twelve Orchids Mr. J. Cypher was first with very large and well-grown plants. Mr. H. James took the second place, and Messrs. Jackson & Son were third. The majority of the nurserymen's Orchids were the same as those noted in our report of the South Kensington Show, except those from Messrs. Jackson & Son, which comprised some good Cattleyas, Cypripediums, Dendrobiums, and Odontoglossums. Mr. J. Douglas also had a handsome example of *Masdevallia Harryana* with about sixty flowers, and Cypripedium caudatum roseum, very fine.

**STOVE AND GREENHOUSE PLANTS.**—An open class for twelve specimens was the leading one, and in this the prizetakers were Mr. J. Cypher, Cheltenham, whose specimens were in capital condition; Mr. J. Mould, Pewsey, second with neat plants, *Statice profusa* excellently flowered; and Mr. H. James third with large specimens. The Cheltenham plants comprised *Pimelea Hendersoni* 6 feet in diameter, *Erica depressa* of similar size, *E. Cavendishiana* beautifully flowered, *Ixora Williamsi* 6 feet across and grandly flowered, *Erica tricolor rosea*, and *Anthurium Schertzerianum* Cypheri with very large spathes.

An amateurs' class for six specimens was included, the exhibitors being Mr. C. Rann, gardener to J. Warren, Esq., Handcross Park, Crawley, first, with handsome Azaleas, *Ericas*, and *Pimelea decussata*; second Mr. G. Wheeler, St. John's Lodge Gardens, Regent's Park, and third Mr. R. Butler, gardener to H. H. Gibbs, Esq., St. Dunstan's, Regent's Park, with small plants. There was also a class for six specimens from nurserymen, and in this the prizetakers were Mr. J. Cypher first with splendid examples of good culture; second Mr. J. F. Mould with small plants, *Erica ventricosa coccinea* minor being profusely flowered; third Mr. H. James.

**PELARGONIUMS.**—The bright flowers of these plants constitute an important addition to the summer Shows at Regent's Park, and formed two pretty banks of plants. The amateurs' collection of show varieties were from Mr. D. Phillips, gardener to R. W. Mann, Esq., Langley Broom, Slough, and Mr. H. Little. The same exhibitors were first and second with fancy varieties, Mr. Phillips' plants being very handsomely flowered, *Roi des Fantaisies*, *The Shah*, and *Delicatum* especially so. Mr. C. Turner and Mr. J. Cypher were the prizetakers in that order for show varieties, and Mr. C. Turner won also first with fancy varieties, all his plants being in admirable condition.

**FINE-FOLIAGE PLANTS.**—Groups of these with Ferns afforded agreeable foils to the flowerin' plants. Messrs. Cypher, Mr. H. James, and Mr. Mould had some large Palms, Crotons, and Cycads, *Kentia canterburyana* from the first named being very handsome. Mr. R. Butler was first with six Palms, *Kentias*, *Corypha australis*, *Seaforthia*, and *Chamerops*, large healthy plants. With Ferns and six variegated plants Mr. C. Rann was first, showing huge *Gleichenias* in the former and several well-coloured Crotons in the latter. Mr. Douglas also showed some fresh Ferns, and Mr. Butler was third with smaller plants.

**TUBEROUS BEGONIAS.**—Messrs. J. Laing & Co., Forest Hill, were first with twelve Begonias, showing good-sized plants of their fine varieties, *Primrose Queen*, Mrs. J. Freeman, rose; *Ball of Fire*, scarlet; *Norma*, Grace Darling, *Stanhurst Surprise*, *White Perfection*, *Princess Victoria*, and *New Colour*, buff yellow.

**CUT FLOWERS.**—These were well represented. Messrs. Paul & Son, Cheshunt, were first with a beautiful basket of Roses gracefully arranged. Roses were also shown by several amateurs. Hardy flowers from Mr. T. S. Ware, and Messrs. Paul & Son, Cheshunt, were very beautiful; the Irises from the same firms and Messrs. Barr & Son being also notable. Mr. J. Douglas was first with a collection of Orchid flowers, beautifully arranged in pots with Ferns, and comprising *Odontoglossums*, *Masdevallias*, *Læcias*, and Cattleyas.

**FRUIT.**—There was not a large display of fruit, and some of the white Grapes were rather green. The Fruiterers' Company's prize for a collection was secured by Mr. Robbins, gardener to E. Dyke Lee, Esq., Hartwell House, Aylesbury, who had some good Melons, *President* and *Vicomtesse Hericart de Tuury* Strawberries, *Alexandra* and *Early Louise* Peaches, *Elrue Nectarines*, *Black Hamburgh*, *Foster's Seedling* and *Royal Muscadine* Grapes not in first-rate condition. Mr. G. R. Alli, gardener to Major Shuttleworth, Old Warden Park, Biggleswade, was first with Melons, showing *McIndoe's Green Flesh* and *Hero of Lockinge*, followed by Mr. J. Douglas and Mr. Robbins.

The best basket of black Grapes was shown by Mr. T. Osman, gardener to W. L. J. Baker, Esq., Ottershaw Park, Chertsey, with *Black Hamburgh*, small in berry but well coloured. Second, Mr. G. Brush, gardener to Lady Hume Campbell, Highgrove, Pinner, with very fine bunches. Mr. W. Mowbray, gardener to Earl of Leven and Melville, Fulmer, Slough, was first with *Buckland Sweetwater*, large and well ripened. Mr. Mowbray was also first with three bunches of black Grapes, *Black Prince* well coloured, Mr. Osman leading with *Black Hamburgh* bearing a good bloom, and Mr. Brush was second with the same variety rather red. Mr. P. Feist, gardener to R. Ashton, Esq., Bishopsgate House, Staines, was first with *Muscadine* of *Alexandria* not fully ripe. Mr. Mowbray was first in the other white variety class with *Buckland Sweetwater*, and Mr. Brush was second with *Foster's Seedling*.

Seven competitors entered with two dishes of Peaches, Mr. H. Hepworth, gardener to H. T. Goodwin, Esq., Maidstone, being first with *Barrington* and *Alexander*; Mr. Osman second with *Gros Mignonne* and *Early Silver*; and Mr. Nash third with *Royal George* and *Gros Mignonne*. In the Nectarine class, Mr. J. Harris, gardener to Mrs. J. H. Vivian, Singleton, Swansea, was first with *Lord Napier* and *Elrue*, highly coloured; Mr. Nash following with *Violet de Hative* and *Elrue*; Mr. A. Miller, Rood Ashton Gardens, Trowbridge, being third with *Hunt's Tawny* and *Elrue*, all of good quality. The only Cherries were from Mr. T. Hare, Wellingore,

Grantham—*Black Tartarian* and *Elton*; Mr. Worthing and Mr. Mowbray, being the exhibitors of Strawberries.

**MISCELLANEOUS.**—The semicircular hanks of plants in the centre of the marquee were very effective, as usual. Mr. B. S. Williams, Upper Holloway, had a very choice group of Orchids and fine-foliage plants (large silver medal). Messrs. John Laing & Co., Forest Hill, had a bright group of Tuberous Begonias, Palms, Ferns, Orchids, and Caladiums (small silver-gilt medal). Messrs. E. G. Henderson, Pine Apple Nursery, Maida Vale, had a group of Caladiums, Dracenas, Ferns, Palms, Todeas, &c. (silver medal). Messrs. Hooper & Co., Covent Garden, had a tasteful group of flowering and fine-foliage plants (large silver medal). Messrs. Hooper & Co., Covent Garden, had a group of Irises; Mr. T. S. Ware a handsome collection of Pæonies (bronze medal); Mr. John Forbes, Hawick, had a large collection of choice named Pansies of fine quality (certificate).

Messrs. J. Carter & Co., High Holborn, showed a collection of *Ixias*, greatly varied in colours (certificate). Messrs. Hugh Low & Co., Clapton, showed a handsome group of Cattleyas, *Odontoglossums*, *Dendrobiums*, and Cypripediums, very freely flowered (small silver medal). Mr. J. Wiggins, gardener to W. Clay, Esq., Kingston, showed a group of Pelargoniums (certificate). Mr. D. Phillips also had a group of Pelargoniums (large bronze medal). Messrs. W. Balchin & Sons, Brighton, had some plants of the bright blue *Leschenaultia biloba* major. Mr. C. J. Salter had a group of well-grown Hydrangeas (certificate).

Messrs. James Veitch & Sons, Chelsea, exhibited a number of new plants and some handsome collections of *Ixias*, *Pyrethrums*, *Anemones*, Irises, Pæonies, and miscellaneous hardy flowers (small silver medal). Messrs. W. Cuthbush & Son, Highgate, contributed an extensive group of greenhouse plants comprising numerous Heaths, *Pimeleas*, *Epacris*, and hardwooded plants, with *Hydrangea paniculata grandiflora* (small silver medal). Mr. May showed a group of small Orchids, and Messrs. Wheeler, Weston & Eason had some well grown Fuchsias. Messrs. H. Cannell and Sons, Swanley, had a small group of choice Gloxinias.

Numerous new plants were shown and many of them were certificated.

## ROSE AND HORTICULTURAL SHOW FIXTURES, JUNE AND JULY, 1886.

THE following are the dates of the principal Shows to be held during June and July this year. The great event of the season will no doubt be the provincial Show of the Royal Horticultural Society at Liverpool at the end of June.

Manchester National Horticultural Exhibition, Old Trafford, June 11th to 18th.

Brentwood, June 17th and 18th.

Royal Horticultural Society Committee meetings and Pelargonium Show, June 22nd.

York Floral Fête, June 23rd and 25th.

Royal Horticultural Society Provincial Show at Liverpool, June 29th to July 5th.

Bagshot and Windlesham Rose Society, at Bagshot, Tuesday, June 29th.

Canterbury and Kent Rose Society, at Canterbury, Tuesday, June 29th.

Croydon Horticultural Show, June 30th.

Royal Botanic Society's Evening Fête, June 30th.

Farningham Rose and Horticultural Society, at Farningham, Wednesday, June 30th.

Croydon Horticultural Society, at Croydon, Wednesday, June 30th.

Reigate Rose Association, at Reigate, Thursday, July 1st.

Tunbridge Wells Horticultural Society, at Tunbridge Wells, Friday, July 2nd.

Brockham Rose Association, at Dorking, Saturday, July 3rd.

Eltham Rose and Horticultural Society, at Eltham, Saturday, July 3rd.

Crystal Palace Rose Show, Saturday, July 3rd.

National Rose Society, at South Kensington, Tuesday, July 6th.

Cardiff Rose Society, at Cardiff, Wednesday, July 7th.

Sutton Amateur Rose Society, at Sutton, Wednesday, July 7th.

Oxford Rose Show, Wednesday, July 7th.

Ealing, Acton, and Hanwell Horticultural Society, at Ealing, Wednesday, July 7th.

Bath Floral Fête and Band Committee, at Bath, Thursday, July 8th.

Ipswich and East of England Horticultural Society, at Ipswich, Thursday, July 8th.

Hitchin Rose Society, at Hitchin, Thursday, July 8th.

Hereford and West of England Rose Society, at Hereford, Friday, July 9th.

Maidstone Rose Club, at Maidstone, Friday, July 9th.

Wirral Rose Society, at Birkenhead, Saturday, July 10th.

Diss Horticultural Society, at Diss, July 13th.

### KITCHEN GARDEN.

**TURNIPS.**—Milan has again proved the earliest of all. We were gathering bulbs of it during the last week in May, and now they are a

good size. They are white, purple tops, good in form, and fine in quality. Turnips are an important crop, and the early ones are greatly relished. We find all good cooks the same in their daily demands for Turnips, and nothing short of an all-the-year-round supply will give satisfaction. Previous to the young ones being ready we were sending in Swedish roots of last year's growth, and although tough they did very well for the stock pot. Advancing crops must be thinned in good time; crowding while young ruins them. A large sowing of Veitch's Red Globe should now be made. It is a useful sort, not very apt to be injured by hot weather, and it remains a long time fit for use. This sowing will be ready for use about the middle of August, and it will keep up a supply until October.

**PEAS.**—We gathered our first dish in the open on June 1st. There were two varieties ready then; one was the dwarf American Wonder, the other a new variety not named, which has proved the earliest medium-growing Pea we have possessed. William I. is falling behind. It has kept its place well, and is still good. Stake all young crops requiring this attention. It is bad practice to allow them to fall over for want of support. Where the weather is very dry water all freely with liquid manure. It is almost impossible to give them too much. Late crops should now be sown. They should have rich deep soil and a warm sunny position. The trench system should also be practised with them, as this will be the means of their keeping strong and healthy during any warm dry weather that may be experienced. Sutton's Latest of All, Laxton's Omega, and Ne Plus Ultra are all good late sorts. The first and second grow compactly, and only attain a height of from 3 feet to 4 feet, but the latter runs up to 6 feet, 7 feet, sometimes 8 feet, and should only be grown where there are tall stakes procurable.

**ARTICHOKES.**—The Globes are very late this season. They are only now beginning to form, and to force them on the plants should have large quantities of liquid manure. Mulching in dry weather is also of much benefit to them. Jerusalem Artichokes are growing freely, but being planted on the same ground as they occupied last year many have come up which have no right there, and the whole of these have been drawn, allowing those only to remain which were planted in rows 3 feet one way and 18 inches the other. A multitude of growths make a fine-looking plantation, but large tubers are only produced by growing the plants quite clear of each other.

**COLEWORTS.**—Where seed of these was sown some time ago the plants will now be ready for putting out, and they should be planted about 15 inches apart each way on ground which has been cleared of early Potatoes or other crops.

**BROAD BEANS.**—These are not ready yet, but they promise well. Where they are wanted as soon as possible pinch the point out of each stem, and this will cause the pods to swell rapidly. Another good sowing of seed should be made for autumn. Carter's Leviathan is one of the finest Beans for late use we have grown.

**KIDNEY BEANS.**—Stake runners as soon as they get out of the seed leaf. They are much better when twisted round a stake than entangling each other, and this occurs when staking is neglected. Sow a row for late use. Dwarf Beans of the Canadian type are rather yellow in colour, the nights being still rather cold for them, but if a sprinkling of soot is placed along each side of the row and a little soil afterwards drawn up to the stems, they will soon attain a deep green hue and grow freely. A little guano water now and again is very beneficial, especially to early rows in dry weather.

**HOEING.**—There can hardly be too much of this done amongst the young crops. It is most serviceable when the soil is dry on the surface, as the weeds are uprooted and soon perish. Weeds are now growing fast in all corners. It is surprising how effectually hoeing checks them. It is the quickest way of all of doing this, and considering how cheap and easy this may be done, weedy vegetable gardens should never be seen. Hoeing down weeds before they have time to seed is profitable labour.

**SEAKALE AND RHUBARB.**—Both of these are now throwing up many bloom spikes, and as these serve no good purpose, unless seed is wanted, every one of them should be cut off before they are in bloom, or at most before they seed. Where really tender young Rhubarb is wanted in July or August, the greater part of the stems may be drawn up, when many young ones will take their place. Where tender Rhubarb is wanted for exhibition, it may always be secured in this way.

**CALIFLOWERS GOING BLIND.**—Some varieties are worse than others for this. On a piece where we have five sorts planted one has almost all gone in this way, while of others we have not lost half a dozen. As a rule, however, it may be prevented by dusting a little lime into the centre of each plant. Where it is noticed that any have lost their centre or gone blind, there is no use in allowing them to remain, as they will never form good hearts, and the best way is to throw the plants away and replace them with others.

**CAPSICUMS.**—These are sometimes planted out, but they do not always succeed in this way, and the best way is to grow them in a frame and where they can be protected with glass when necessary. There are now empty frames in most gardens, and one may be filled with these. If the frames contain the remains of old hotbeds, the plants may be turned out of the pots and placed in the old soil, but where the frames are empty they may be grown in 7-inch and 8-inch pots. Frequent syringing and plenty of water at the root suits them well when in full growth.

**MUSHROOMS.**—These have been a great success with us this spring. We grow them in cool sheds and find them do admirably there. We made the best bed up about the middle of January; it began bearing by the third week in February, and did not cease doing so until the middle of

May. A three-months supply from one bed is very satisfactory, and the numbers we cut were extraordinary. The cool system quite surpasses the warm one for them; indeed, we have ceased to use our heated Mushroom house and adhere wholly to the natural temperature of the shed. Beds now bearing or beginning to fruit should be kept rather moist, and the surface should always be incased in a coating of hay. This prevents the soil from drying readily, and it also protects the young Mushrooms. As warm weather sets in worms are very apt to work their way up through the stems and into the heads. These are then useless, and many Mushrooms may soon be ruined in this way. A good preventive, however, is dissolve about one tablespoonful of salt in two gallons of water, and water the bed completely with this. It should not be given cold, but heated to 80°.

#### FRUIT FORCING.

**PINES.**—*Fruit Ripening.*—When the fruits commence colouring syringing must cease, but the supply of moisture or water at the roots must be maintained, affording it whenever necessary. With a view to improve the quality of the fruit ventilate whenever circumstances permit, but do not allow the temperature to fall below 80° in the day, applying fire heat to maintain a night temperature of 70° to 75°, gradually reducing the moisture in the house. Queen and Providence Pines started into fruit early in February will ripen this month, coming in about three weeks or a month before Smooth-leaved Cayenne, Charlotte Rothschild, and similar varieties started at the same time and under similar conditions. They afford a good successional supply, which may be still further extended by removing some of the plants with the fruits to a cooler house. Although the Providence Pine is not nearly equal to a Queen in quality, yet its size being superior, a limited number should be grown, as large fruits are very useful at parties if only for effect in table decorations. The heat at the roots must be kept at 85° to 90°.

*Plants for Winter Fruiting.*—The strongest of the plants put in the fruiting pots last September will now be showing fruit; if not, means must not further be delayed to effect it for a supply of this once highly prized and now much-neglected fruit for winter use. The plants should be brought together and subjected to a comparative state of rest for the next month or six weeks, lowering the heat at the roots to 75°, maintaining a free circulation of air about the plants in favourable weather, ventilating at 75°, and allowing the heat to fall to that degree before closing the house, only employing artificial heat to prevent the temperature falling below 60° at night, not withholding water altogether, but wherever a plant becomes dry afford it liberally. The smaller suckers of last autumn that were wintered in 7 or 8-inch pots, and shifted this spring, must be kept growing until the pots are well filled with roots, at which time, if considered necessary, they may be subjected to the same treatment as advised for the larger ones, and these plants will then give a successional supply of fruit.

*Ventilating, Watering, Shading, &c.*—Young stock will be making rapid progress, and should be regularly attended to in every particular, allowing such plants sufficient space for development, as nothing is so injurious to a sturdy growth as crowding in the early stages. Ventilate early in the day at 75° to 80° to render the foliage dry before it is affected by the sun. Examine the plants twice a week for watering, not giving any until it is needed, and then a thorough soaking with tepid liquid manure, being careful not to give it too strong. Discontinue shading succession plants, but fruiting plants with the crowns in close proximity to the glass will require a slight shade from powerful sun. Syringe the plants on bright afternoons, and otherwise maintain a genial condition of the atmosphere by sprinkling the house; but avoid much moisture in dull weather, as it only tends to cause soft growth. So long as water remains in the axils of the leaves syringing is not so much required, and in watering pour the water well up the plants, as the axils of the leaves at the base have roots that contribute to the vigour of the plants and swelling of the fruits.

*Spring-potted Suckers.*—The strongest of those potted last March should be in their largest pots; if not, there must not be any further delay, as to allow them to become much root-bound is debilitating and detrimental to their after well-doing. Recently potted plants should have a regular bottom heat of 85° to 95°, and be thoroughly watered after potting, not giving any more until the soil becomes dry. A too-wet soil is not favourable to the formation of roots.

*Potting Suckers.*—The early-fruited plants as they finish will afford suckers, which should be taken in sufficient quantity to meet the demand and started at once, which will afford plants for fruiting about this time next year, forming a supplementary batch to those started in spring. The treatment then given will answer for these, only they will require more careful shading and frequent attention to damping.

**MELONS.**—*Fruit Ripening.*—Plants with the fruit ripening should have a plentiful supply of air, and water should be withheld from the fruit. If the plants are strong and there is a disposition to crack, in addition to withholding water from the roots cut the bine carrying the fruit half and not more than three parts through a few inches below the fruit. A dry atmosphere is essential, and a temperature of 70° to 75° artificially, falling about 5° at night. If the sun be very powerful place a slight shade of some kind directly over the fruit, as Melons ripening become heated, and do not ripen nearly so regularly nor become so high in flavour as those that come on more gradually. Water need only be given to prevent flagging, and a slight shade from bright sun after a dull period is much the better way to prevent flagging than heavy watering and a close vitiated atmosphere.

*Fruit Swelling.*—Add more soil to the hillock or ridges. Let it be

warm, moderately moist, rather heavy, and press it down firmly. Give a thorough soaking of water as soon as the fruit is the size of an egg, and follow in the course of a day or so with tepid liquid manure, then mulching with horse droppings, exposed for a few days in an open shed and turned over daily. Water will be required about twice a week, or only once in dull weather. In narrow borders the waterings will need to be more frequent; in large borders, or beds over fermenting materials, it will not be needed so often. Remove all fruit but three or four on a plant, and all staminate and pistillate blossoms, and afford the needful supports. Stop or remove laterals freely—not great reductions at a time, but little and often, not allowing secondary and tertiary growths to interfere with the principal. Syringe twice daily—in the afternoon not later than four o'clock, having the foliage fairly dry before night, and sprinkle the house about 5.30 to 6 p.m. with water if the droppings are used, or if not with liquid manure, and give a little ventilation at the top of the house when looking round the last thing at night. This will save some trouble if no air is given early in the morning. On bright mornings commence ventilating about seven o'clock, or at 75°, and increase it with the advancing sun, keeping through the day at 85° to 90° with bright sun, and 80° to 85° with alternating gleams. Close at 80° to 85°, running up to 90° or 95°. Fire heat will only be necessary on cold nights and in dull weather, for we must guard against a sluggish circulation of sap.

*Plants Setting Their Fruit.*—The plants should be thin in foliage that the light and air has free access. The growth will be stout and short-jointed, and the leaves stout in texture. The blossom will be strong. Ventilate a little constantly, and if dull have sufficient warmth in the pipes to cause a circulation of air, and falling below 65° at night or 70° to 75° in the daytime. Withhold water from the roots, but the soil must be sufficiently moist to prevent flagging, and only moderate moisture will be required in the atmosphere, damping in the morning and again in the afternoon, but keep it from the plants and blossom. To prevent the deposition of moisture on the blossom provide a warm buoyant atmosphere. Fertilise the blossoms about noon of fine days, and when several blossoms are expanded on a plant, so as to insure uniformity of swelling, stop at one joint beyond the fruit.

*Young Plants.*—Train with one shoot for trellises, and rub off the laterals up to the first wire, and then every alternate one on opposite sides afterwards, stopping the leading shoots when about two-thirds up the trellis. Flowers ought to show on the laterals; if no blossom shows at the second joint stop at that. Plants for training over the surface of the bed should be stopped at the second leaf. Select four of the resulting shoots, training two to the front and two to the back of the frame or pit. Remove all others carefully with the point of a knife, but if only two shoots result stop them at the second or third leaf and make selection of the best for training as before advised. Keep the stem clear of laterals and leaves for a space of at least 6 inches from the collar. Remove every alternate lateral on the shoots, stopping the shoots when 12 to 15 inches from the sides of the pit or frame. Let there be no deficiency of moisture at the roots, and add fresh warm soil to the ridges or billocks as the roots protrude, but the soil being put in in quantity as advised none will be required in pits or frames utilised for Melons after Potatoes and bedding-out plants. Syringe at closing time, but avoid wetting the stems, as it may lead to canker, which should be kept under by rubbing quicklime into the affected parts until dry. Keep the house well ventilated, so as to insure a short-jointed sturdy growth. Continue to put out plants as pits or frames become vacant, and if a gentle warmth at the roots can be afforded it will give the plants a start and be all that is necessary. Close early and keep the growths well regulated, not less frequently than once a week. Shade only to prevent flagging; it will only be necessary for an hour or two at midday under powerful sun.

*Sowing for Late Fruit.*—A last sowing should be made at once for planting in dung-heated frames or pits, the plants from which will be useful for getting successions where crops have already been taken, or being taken, and the plants are not kept from collapsing through red spider or other disaster. Plants from this sowing will afford useful fruit at the latter part of September. Those with light well-heated structures may continue to make sowings as required up to the end of July. The plants from the last-named will continue the supply up to the beginning of November, after which it is useless thinking of having fruit of good quality.

*FIGS.—Early-forced Trees.*—Generous treatment will be needed after the first crops are gathered to enable the trees to swell the second. Syringe twice a day to keep red spider in check, and afford liquid manure when watering is necessary, trees in pots requiring it daily, sometimes twice a day, and trees in borders once or twice a week, according to the extent of the rooting area. The second crop should be thinned before the fruit is the size of walnuts, and in thinning reserve the largest fruit at the base of the shoots. Mulch trees in pots with rich material.

*Succession Houses.*—When the fruit commences to ripen, a free circulation of warm dry air should be afforded, which is essential to high quality, not less so being the tying-in and regulating of the shoots by thinning and stopping, so as to afford the fruit the benefit of all the light practicable. The moisture in the atmosphere will need to be moderated, not wetting the fruit; though if red spider attack, the fruit should be gathered closely and a good syringing given, which will not injure the remaining fruit, provided it is done early on a fine day, so that the moisture does not remain long on the fruit. Do not allow any lack of water at the roots, yet give lessened supplies than when the fruits were swelling.

*Young Trees in Pots for Next Year's Early Forcing.*—These must not be neglected or disappointment is inevitable. They must have all

the light possible, and be kept as near the glass as practicable without touching, so as to secure sturdy well-ripened growth, keeping clean by syringing, and affording liquid manure to effect a stout growth. The growth complete, they may be stood outdoors to induce rest, but the wood must be well ripened previously, and to be of use for early forcing the wood must be matured early.

#### THE FLOWER GARDEN AND PLEASURE GROUND.

*Late Bedding Out.*—The very unfavourable weather experienced of late will have had the effect of retarding this work, and on the whole the majority of the plants will succeed all the better for being kept out of the cold and wet ground for a time longer than usual. Those that were planted early look very miserable indeed, and will be some time before they form fresh roots and growth. Take the first opportunity of loosening the surface of the soil about them, and this will let the air and warmth into the roots, and at the same time arrest rapid evaporation and cracking of the soil. Many probably are only just commencing in earnest, and these may now complete the beds as they proceed, Iresines, Coleuses, and other tender plants having now been sufficiently hardened off to admit of their being planted out. Should, however, the weather still remain cold, spaces ought to be kept for them, and the planting deferred for a few days longer. The outer rings ought always to be planted first, finishing in the centre. Those who have had but little practice in planting ought to have the lines marked for them either with the back of a rake or with large wooden compasses, the latter being especially useful for giving correct marginal lines. If it is proposed to peg down the plants in order to make them cover the ground evenly and neatly, all the strong growers, such as Zonal Pelargoniums, Calceolarias, and Iresines, should be planted in a sloping direction, this rendering them less liable to snap off.

*Odd Corners.*—There are many corners that have to be filled after the principal beds are completed, and for these there are frequently an insufficiency of plants. When this happens with us we fall back upon the old stock plants of Heliotropes, Ageratums, Verbenas, Iresines, Abutilons, Petunias, and such like, supplemented, if need be, with strong old pot plants of Fuchsias, double and single Zonal Pelargoniums, Plumbago capensis, Begonias, and Marguerites, and these judiciously mixed not unfrequently surpass in attractiveness the more formal beds. As many of the plants used are in the first instance in a semi-starved state, we take the precaution to add some rotten manure or plenty of leaf soil to the beds or borders, as without this the plants make but poor progress. Corners are generally neglected as far as renewing the soil or manuring is concerned, hence the stunted appearance of the plants occupying them. Strong pot plants when first planted soon get dry at the roots, and this should be guarded against, mulching with leaf soil, short manure, or other material, in addition to occasional waterings, which are necessary in most seasons.

*Carpet Beds.*—These are generally taken in hand after the other beds are nearly completed. If the hardy neat-growing plants forming the groundwork are already planted the work of filling in the figures is a comparatively simple matter, and an immediate effect is the result. As the Sedums, Menth, Antennaria, and Herniaria have necessarily to be pulled to pieces prior to planting to insure a neat and well-covered surface, it follows that if this is done in hot sunny weather they must be properly fixed in the soil, be frequently lightly watered overhead, and be shaded from bright sunshine for a time. Thus treated they soon become established and will spread rapidly. As the lines have to be very neatly planted, the use of the trowel has to be discontinued, the dibble being the best tool for the work. Small plants of Golden Pyrethrum direct from the seed bed are the easiest to plant, and they should be disposed about 2 inches apart. If disposed further apart they grow too coarsely, and are not so easily kept to a fine line. Alternantheras may also be planted with a dibble, or better still with the hand, and they should just touch each other all round, as they sometimes get smaller instead of larger when first put out. Our plants are strong ones, but the large leaves soon disappear, and are replaced by neater and more highly coloured shoots. Alternanthera paronychoides major is a good dwarf yellow sort, while A. magnifica and A. amœna spectabilis are very richly coloured and distinct. Lobelias are apt to fail early in the autumn; but in large figures L. pumila magnifica is sometimes used with good effect. Ageratum Cannell's Dwarf is very neat and floriferous, and is well adapted for carpet beds. Iresines as a rule are too tall, but I. Lindeni can be used in large figures. Single plants of Echeverias metallica and metallica glauca, Pachyphiton bracteosum, Agave americana, Chamæpse diacantha and Cassabonæ, Centaurea ragusina compacta or candidissima are suitable for planting singly in the centre of circular figures, or for dotting among dwarf plants in large figures, while for the centres of dwarf plants of Grevillea robusta and, better still, Cordyline indivisa, are effective.

## THE BEE-KEEPER.

#### PLACING AND REMOVING SUPERS.

At pages 430, 431, "Felix" gives very plain and valuable instructions regarding placing and removing supers, and desires to learn whether I can give any other "useful hints" that he has not mentioned. I fear I cannot from the standpoint he takes, but I will take

the salient points of his article seriatim. Before doing so I will endeavour to make plain to your readers that the construction of his and my hives are apparently different, which makes a great difference in the mode and ease of manipulation. All my hives are smooth on the upper surface, and bees are admitted to the supers from the outside spaces only. This secures—if the stock hive is large enough—an entire immunity from brood in the supers; purity of comb is secured by the absence of the vitiated air that ascends from the centre of the brood nest, which should be free from draught, and as a rule the combs in the supers will not be attached to the crown of the hive. Supers so detached are prettier and easier managed, both in the on-putting and the taking off. In the former case I can assure bee-keepers that gloves irritate the bees, and more bees are killed by their use than without them. My plan is never to approach a hive if the bees show signs of spitefulness without taking means to quiet them. Nothing is better than carbolic acid. Smear the alighting board with it in such a manner that it will not injure the bees, and slip beneath the combs some sheets of carbolicised paper. This will at once subdue the most vicious bees. Smoke with me is a thing of the past. It irritates the bees and affects the honey in the hive, and cannot do otherwise than injure the brood. When that operation is past uncover the hive, and if the operator is timid have more pieces of carbolicised paper. Place these at the sides of the slides or whatever closes the opening, then place the supers and cover as directed by "Felix." Supers on Stewarton hives can be placed first, then the slides can be withdrawn after, thus securing the timid bee-keeper an entire immunity from stings. Stand behind the hives in all your manipulations. If any of the hive tops are not made after this fashion do so the first opportunity. Wide holes in the centre of straw hives and narrow top bars of frames give the bees a great deal more labour, irritating them much whenever manipulated, and the beauty of supers is destroyed.

Bellglasses are a sort of luxury some bee-keepers have a desire for, but are unprofitable and difficult to handle. I cannot recommend these to be used on any hive unless on a straw hive expected to swarm. Very often a good-sized super will be got from such a hive, and yet not retard the occurrence a single day, and is likely to be finished in greater purity after the exodus of the swarm by the remaining but fewer bees. From the slippery nature of the glass the bees are more liable to fasten their combs to the top of the hive than when wood is used; but where they are not allowed to build their combs upwards very small attachments will be the result.

When it can be carried out 3 P.M. is the most suitable time of the day for all manipulations. At that time the heat is greatest and the bees are busy and less inclined to rob. If honey is not plentiful the bees are not only more irritable, but are liable to rob; when plentiful are neither. The removing of a bellglass requires more care than that of a super. If thoroughly finished the bees retreat downwards, but very often a great many bees cling to the combs, and if there are no broken cells they begin at once and nibble the seals, destroying the appearance of the comb, and if young bees are in it, which is often the case, are liable to soil the combs after they have gorged themselves with the honey.

To get the bees quickly and successfully out of these glasses, and to prevent the comb being broken or soiled, is the work of the bee-keeper. If the day is warm and the honey is coming in plentifully there is little or no difficulty in getting the bees out. Immediately the glass is inverted the bees will leave it and enter the cap held over it; but if the weather is unfavourable then the bees cling to the comb and will leave it reluctantly.

The moment a bellglass is detached from the top of the hive slip a carbolicised paper in a line as the combs run until all is covered, unless opening enough to allow the bees to pass downwards into the hive. This operation is easily performed if three wedges are used to support the bellglass—one in front and at each side, leaving the back part open for paper. Another plan is to slip a cardboard or piece of wood fitted with a trap, and set it in a box or on a stand close to the hive and cover thoroughly. The bees will leave as well as the queen, should she happen to be in the glass, and pass out and into the hive (if a gangway has been provided) without the loss of a single bee or jar to the bellglass. If there is any likelihood of the bees in the glass breaking the seals have a furrow or two on the top of the board, and put a little liquid honey in them; the bees will sip this and the seals will not be interfered with.

Removing supers is, comparatively speaking, mere child's play. They must, however, be all of the divisional sort. Close crowns should not be tolerated in the apiary; tiering cannot be performed with them while the bees are as difficult to get out of that sort as from bellglasses. When removing supers of the right sort we care not what sort of a day it is nor what time. Before packing up our supers we cover the top ones with a piece of white calico. Having the carbolicised paper sheets in readiness, we uncover the top of the supers (after a card or wire has been passed between each tier or

top of hive), beginning at one side, slipping in the paper as each opening appears, from which not a bee need escape. By the time the last paper put in is withdrawn, which may not be longer than a minute, there will not be a bee left in the super, and no seals broken.

When is a hive ready for supering? This is an important question. No hive is ready for supering unless it has its complement of bees in a full-sized hive. If hives are undersized little good can be got from them beyond a pigmy super. If full-sized and of full strength the sound of the bees at night, together with the weather, indicates the proper time to super, but unless crowded better not to be in too great a hurry. The number of supers to be kept on a hive depends upon the abundance or the paucity of flowers in the locality as well as that of the hive of the season. If at the beginning more super space may be given, but if further on less. The bee-keeper must exercise his own judgment in this, and learn how much super space his bees are likely to fill during the season the honey is likely to last. We generally build up by degrees (the small supers are best adapted for this work), and we have had frequently from 100 to 200 lbs. of supers filled and on at a time.

The plan of raising the first-put-on super and placing an empty one beneath is not objectionable if the weather is and continues fine, but if that is not likely to be it should not be attempted, because the bees will make an effort to fill the vacuum at the expense of the raised super. With the little supers I work them by lifting nearly full ones, placing these over other filled or partly filled ones, and adding empty ones on the most convenient place over others advancing. By this means I manage at times to get some off quicker; but as a rule the honey season lasts so short that no supers are finished; nor ought they to be interfered with till the season is past, but remove as soon as the bees become inactive, or the comb will become discoloured.

A one-windowed room is doubtless a good place for manipulating bees, which I often take advantage of; but a chest having a pane of glass in which to place the supers as they are taken from the hive I much prefer, because the bees find their way more readily to their hive, and are easier caught and carried to it than when they are allowed to escape by the window, many of which must necessarily be lost because of their youth, perhaps never having flown, but the carbolic acid obviates all risk. To what "Felix" has said with the above remarks nothing need be added. If we do not quite agree it is because our hives and appliances are different.—A LANARKSHIRE BEE KEEPER.

P.S.—The weather still continues cold and damp. The thermometer on the morning of the 27th May stood at 25°. There has been only four days during the whole month the bees could venture out. My hives are all ready for swarming or supering, and queen-rearing, which should have been going on, is at a standstill owing to the extreme cold. I have fed none yet, but shall be compelled to begin soon unless genial weather sets in. Hives allowed to go back now will be unprofitable. It is better to feed in time than to allow any to suffer from want.—L. B. K.

#### INTRODUCING QUEENS.

"A SURREYSHIRE BEE-KEEPER," page 411, says, "When we consider the life history of the bee, it is sometimes difficult to know which to admire most—its wondrous wisdom or its fatal folly. At times it would seem to possess the power of reasoning, at other times it seems deprived of the slightest evidence of instinct. Take, for instance, the behaviour of bees when deprived of their queen. One would imagine that they would only be too thankful to accept the first one offered to them, but, on the contrary, they will frequently sting her to death, or suffocate her by balling, even when she has been caged for forty-eight hours . . . and the older the bees the more difficult it is to introduce a queen." Then he gives elaborate directions for introducing one, which reads like a passage in some old work on alchemy, and winds up by saying, "Unless obliged, we do not attempt to introduce queens either in early spring or late autumn. Bees are kittle cattle; no method has yet been found to be infallible."

After reading such remarks by one who presumably examines and grants experts certificates of competency in bee-keeping on behalf of the British Bee-keepers' Association, it is quite refreshing to read the first paragraph in "Lanarkshire's" article, which follows that referred to above.

Had "A. S. B. K." not been such a great authority in bee matters, and so important a one, that his letters in this Journal are made use of in the *British Bee Journal*, I would have treated his letter as by a novice, but instead, I must, in the interest of progressive apiculture, take him to task for being behind the times.

He has said, a fresh queen cannot readily be introduced to old bees, nor in early spring or late autumn would he have us to accept the absurd theory that if bees had no means of rearing a queen, that Nature had ordained that the stock should die off, and if a strange queen should happen to come to them (say one lost on her bridal trip, which often happens) that the bees should "ball" her to death. Such a teaching

is quite contrary to all the laws of Nature, and would stand alone. But that the contrary is the fact any bee-keeper can prove for himself, if he will bear the following law in mind—viz., "That when bees are queenless, and have no means of rearing one (that is, have no eggs, unsealed brood, or queen cells in their hive) they will invariably accept a fertile queen at the flight hole, or dropped in from the top," provided they have been queenless forty-eight hours. There needs no book-writing for this system of direct introduction, as the practice can be varied to suit all cases, and nothing but the simple rule need be remembered to introduce a queen by it at any time of the year. I have used it for years at all times of the season, and never had a single failure, and none ever will have a failure, unless he is operating on a stock of bees as stupid as your correspondent thinks they are. No matter how old the bees are, or how long they have been queenless, you may safely let your most valued queen run in at the entrance.

This simple system is particularly valuable in the fall, when hives are broodless, or nearly so. The queen I am going to introduce I keep in a Benton mailing box with a few bees. The old queen I remove, and carefully look for eggs or unsealed brood at same time. If I find any I put it into another hive, then any time after forty-eight hours I give them the queen, and take no further notice of them. In summer, if I wish to divide a stock on purpose, I place a hive containing a few empty combs on the old stand, and move the stock to a fresh one, thus I catch all the old bees, and if not sufficient, then I shake in a few young ones from the old stock, being careful not to get the queen—these old queenless bees will always accept a stepmother after forty-eight hours—after which I should give them some combs of sealed brood. If it is not wanted to divide a stock, and it contains eggs and brood, say in early spring, and it is not advisable to give it to another stock, the queen cells started should be carefully cut out on the ninth day after removal of the old queen, when the fresh one could be given them forty-eight hours afterwards. It is not necessary to await the arrival of the new queen before removing the old one, or she can be kept in a mailing cage. A friend of mine introduced a queen under this system at the beginning of May that had been queenless all winter, which I found on the 29th of May in a most prosperous condition. He could not have introduced one by caging, but with this, novice though he was, success was certain.

This method, or "law" rather, is not a new notion, but one that has been tested for years. Let all try it, particularly novices, and then they can say whether "bees are kittle cattle," or "no method has yet been found to be infallible," or not. Of course this method puts no grist in the supply dealer's mill, not even the price of an introducing cage, or a repetition of order through the other queen being lost, therefore it has been for years neglected by the writers in the *British Bee Journal*, whose editor, I see, in a reply to a correspondent, page 238, May 27th, says, "Worker bees do not store anything in their cells but honey." No doubt some novices will ask if they do not also store pollen and water.—A HALLAMSHIRE BEE-KEEPER.

#### TRADE CATALOGUES RECEIVED.

Messrs. Boulton & Paul, Norwich.—*Illustrated List of Garden and Poultry Appliances.*

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**TO CORRESPONDENTS.**—We desire to assure those of our correspondents whose letters and communications are not promptly inserted that they are not the less appreciated on that account. Our pages are practically filled several days prior to publication, and letters arriving on Wednesday morning, except by special arrangement, are invariably too late for insertion. The delay in the publication of some of these is not of material importance, but reports of meetings and shows held a week previously lose much or all of their value if not received in time to appear in the current issue.

**Books (Joseph Smith).**—Probably Thomson's 'Fruit Culture Under Glass' will meet your requirements. It is published by Messrs. Blackwood, and can be obtained through a bookseller. (E. A.).—The fourth edition of

'Mushrooms for the Million,' with supplement, is in the press, and will shortly be published. Though the work will be materially enlarged, there will be no increase in price—1s. 2d. post free.

**Address (W. H. Strive).**—Your letter has been received and forwarded to the advertiser of the articles. (J. E. T.).—If you enclose a postcard addressed to yourself, we will give you the information you require.

**Wood Ashes—Chemical Manures (H. S. S.).**—You will find the information you require in our reply to "F. J.," on page 451 last week, and which had probably not reached you when you posted your letter.

**Manure for Grass (L. S. G.).**—You would find on page 456 the information you seek, and which had not reached you when you penned your inquiry. The ingredients can be had from manure dealers in various districts.

**Sowing Seeds of Bulbous Plants (W. A.).**—You cannot, perhaps, do better than sow the seed in sandy soil, well drained, early in October, and the seedlings ought to appear in the spring; that will be better than deferring the sowing till March or April.

**Transplanting Strawberries (J. E.).**—The best time of planting such large plants is as soon as possible after the autumn rains commence, or in time for the plants to make fresh roots freely before winter. If disturbed in the summer, and a term of hot dry weather follow, they will be slow in getting established, and may be considerably weakened. The leaves should not flag after removal. We are obliged by your letter.

**Management of Fruit Trees (H. P.).**—The sentence to which you refer—namely, "Close prune spring growth, but only shorten midsummer growth sufficient to admit air and light freely to the spurs," is included in an article under the heading of "Hardy Fruit Garden," in the *Journal of Horticulture*, page 225, September 4th, 1884. The number containing the article is out of print, but it can be referred to in vol. ix., new series. It was written by a very successful cultivator of hardy fruits.

**Seedling Mimulus (W. F. B.).**—We have seen flowers similar to those before us, but not exactly like them. The habit and floriferousness of the plant must be taken into account in estimating the merits of a variety, and the best advice we can give is that you grow a few plants well and exhibit them, as in no other way can the commercial value of a new variety be so well ascertained. You can of course send flowers to florists, but we doubt if they will offer you any substantial sum for the stock from a sight of the flowers alone.

**Pansies Dying (J. P.).**—The cause of the sudden collapse of Pansies cannot be exactly defined. It is a very old "grievance," and assuming the plants are established in good time and not twisted by the wind, there is either something in the soil that is injurious, such as grubs, or it is defective in some constituent that is requisite for the continued support of the plants. Those planted late in the spring are the most liable to "go off" prematurely, while they fail in one part of a garden and succeed in another. If you are especially anxious to grow them on the particular plot in which yours fail, you will not be likely to succeed unless you remove a great part of the old soil and introduce fresh of a suitable nature. This at least is what experience has taught us in failing and succeeding in growing these flowers. It is always the best to grow them in that part of a garden in which they "naturally do well."

**Adiantum cuneatum for Market (D.).**—This Fern is usually grown in 5 and 6 inch pots in the London Fern-growing nurseries, but some plants are shifted into larger pots. The plants occupy side beds in low houses or pits, and are stood upon ashes or some other moisture-holding material. They must have room to develop their fronds and pay very well for good cultivation. We should not expect the plants to do satisfactorily if crowded together. They can stand moderately thick, and room can be materially saved if all the old or saleable fronds are removed from the plants instead of cutting a few here and there over the whole hatch of plants. The plants from which the fronds have been removed can be stood thicker together while they develop others. Those from which the fronds have not been gathered can be given more room until ready or wanted for cuttings. This Fern is improved by dividing and repotting in spring. This practice supplies a fresh medium for new roots, and they do much better again when once established. If they have been in 5-inch pots the ball should only be cut into two parts and each half potted into a 6-inch pot. Feeding is beneficial after the pots become full of roots, but we prefer some fine artificial manure, such as Standen's and others to liquid for them, the former being easily applied, and acts very quickly upon the plants; this is what is wanted. A little sprinkled on the surface every three weeks after the pots are full of roots will be ample for them. There is another point of great importance in growing these Ferns for cutting, and that is, that new stock must be raised occasionally. By continually picking the fronds from them as they are fully developed the plants in time become exhausted, in fact they are much less vigorous and will fail to yield the same quantity of fronds. Seedlings grow very freely and some should be raised yearly to replace the weakened plants. If we were growing fronds for market we should always have a quantity of young plants coming forward. A large stock of plants can soon be raised by this method in constantly damp soil and a close shaded and moist position.

**Election of Strawberries (Aberystwith).**—There is no number of the Journal disposable from this office that contains an election of Strawberries. The following is the result of an election conducted by the Rev. C. P. Peach some years ago, with remarks appended indicating the merits and requirements of the varieties:—1. Sir J. Paxton (Bradley).—Named by eight; placed among the first three by three, with sixteen votes in its favour. Medium season, fine quality, good bearer. 2. President.—Named by eight; placed among the first three by two, with fourteen votes recorded. Medium season, good quality, free bearer. 3. British Queen (Myatt).—Named by seven, with seven votes. Medium season, fine flavour. Requires strong soil. 4. Dr. Hogg (Bradley).—Named by six, with ten votes; placed among the first three by two persons. Medium season, fine flavour, large fruit. Requires strong soil. 5. Cockscorn (Royal Gardens).—Named by six, with ten votes. Medium season, very large fruit. 6. Eleanor (Myatt).—Named by five, with eight votes. Large fruit, late season, good cropper, inferior

flavour; placed in the first three by one person. 7. Lucas (De Jonghe).—Named by four, with six votes; placed among the first three by one person. Mid-season, five flavour, good cropper. Requires good soil. 8. La Constante (De Jonghe).—Named by four, with seven votes. Mid-season, small fruit, good bearer. 9. Elton Pine.—Named by four, with five votes. Late season, medium bearer, sharp acid flavour. 10. Frogmore Late Pine.—Named by four, with four votes. Late season, good bearer, medium flavour. Requires strong soil. 11. Filbert Pine.—Named by three, with four votes. Mid-season, fine flavour, good bearer. Requires good soil. 12. Early Prolific (Roden).—Named by three, with five votes. Early season, fine quality, good cropper. 13. Vicomtesse Héricart de Thury.—Named by three, with five votes. Medium early, good bearer, medium quality. 14. Prince of Wales (Ingram).—Named by three, with four votes. Spoken of very highly by Mr. Marsden for light soils. 15. Black Prince.—Named by three, with four votes. Early, small, poor quality. 16. Sir C. Napier.—Named by three, with four votes. Mid-season, medium quality, good bearer. 17. Mr. Radclyffe.—Named by three, with three votes. Mid-season, good quality, fair cropper. Requires strong soil. 18. Keens' Seedling.—Named by three, with three votes. Early, medium-sized, poor quality. The following have been named by two persons:—Empress Eugénie, alias Black Bess, Eclipse, Wonderful, Crimson Queen, Rivers' Eliza, Bicton White Pine; the following once:—Scarlet Pine, Sir Harry, Guinevere, James Veitch, Her Majesty, Souvenir de Kieff, Belle de Paris, Aromatic, Rifleman, Jucunda, Marguerite, Premier, Garibaldi, Duke of Edinburgh, Admiral Dundas, Amateur, Bonne Bouche, and Waite's Seedling. Of these Amateur, James Veitch, and Aromatic are as yet little known, and likely to prove very serviceable; and Scarlet Pine, Crimson Queen, and Bonne Bouche are fine-flavoured sorts worth growing, especially in large gardens. We may consequently select the following:—Early.—Early Prolific (Roden), and Vicomtesse Héricart de Thury. Medium.—Sir J. Paxton, President, British Queen, Dr. Hogg, La Constante, Cockcomb, Lucas, and Filbert Pine. Late.—Elton, Frogmore Late Pine, and Eleanor.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (Somerset).—1, *Carex hirta*; 6, Too young to be determined; 3, *Carex vulgaris*; 4, *C. muricata*; 5, *C. sylvatica*; 6, *C. remota*.

#### THE FUTURE OF FARMING.

A RECENT inspection of several farms has deepened our conviction that the future of farming will witness considerable curtailment in the size of farms, and a more just proportion of capital and acres than has prevailed hitherto. There can be no question that the capital of many a farmer has been spread over too wide an area to be fully effective, even in the most palmy days of farming, and under the depression it is precisely upon such holdings that we find numerous cases of bankruptcy irrespective of the size of farms. That plurality of holdings was a safe proceeding twenty years ago there can be no question so far as tenants were concerned, but subsequent experience has shown that it was an unwise one on the part of landlords. Straitened means from falling prices induced many a man to "take it out of the land," with certain vague hopes of better times—hopes doomed never to be realised. The land was farmed out, fell upon the landlord's hands exhausted of fertility, foul with weeds, and not unfrequently water-logged. What this means for the landlord is fully realised by the home farmer, falling as it often does to his lot to take up such farms and bring them back into good condition again. A farm which we now have in cultivation, when it first came in hand was so foul that nothing could be sown during the first year, and nearly a thousand pounds was spent in steam cultivation. Then followed drainage, for it was a heavy land farm, most of it "wet," yet it was intersected by plenty of deep ditches, and the surface of all the fields inclined sufficiently to the ditches to render sufficient drainage a simple matter enough, but it must not be forgotten that it had to be paid for. Manure was another heavy item of what may be termed necessary preliminary expenditure, for the land was very poor, so that altogether there was an outlay of some £3000 to clean, drain, manure and crop this farm. Glad were we when it began affording some returns upon our expenditure, and we hope this season to realise a fair margin of profit.

It may be thought that a faithful steward would never suffer the property entrusted to his supervision to fall into such wretched plight, but when land is held under a long lease and the rent is paid regularly as it becomes due, it is by no means an easy matter to interfere with effect. Under rent reductions and modified agreements, yearly tenancies are fast replacing long leases, and it is clearly in the interest of the owners of the land that it should be so. In the interest both of the owner and occupier of land we require a prospective tenant to afford proof of having sufficient capital to farm the land well. Would that we could also apply a preliminary test of his practical knowledge of farming, but that in most instances has to be taken for granted. Industry combined with good sense enables a man to turn money and labour to best account. We had a pleasing example of this in our farm inspection, to which we may call attention here. The tenant of a small compact farm of eighty acres entered upon his holding four years ago at a rent of £80 a year. He found the land so poor and foul that the first year's rent had to be paid out of capital, and as he told us he was much disheartened, and would probably have broken down, but he fortunately has a good wife, a notable woman, who with the proceeds of her dairy and poultry has helped her husband over the difficulties which threatened to overwhelm them. "I

and my wife work hard fourteen hours daily," said he. We had pleasing evidence of the fruits of their industry and dogged perseverance as we went over the farm, and we were able to congratulate him upon having the most flourishing crops we had seen this season. Such a tenant deserves encouragement, and assuredly he shall have it. He wants more land already. By next Michaelmas he will be ready for more, and arrangements will be made to meet his wants from land in hand adjoining his farm. He has been badly treated and naturally complains of it, yet such a tenant is a landlord's best friend, and he must for every reason have due respect and attention accorded him. More than this, it is in the very nature of things that he should be ambitious; be it our study so to meet his demands, that he may see it is for his interest to keep to the estate under our care and not to seek for a second holding upon another estate. That is a thing which frequently happens and which we greatly deplore, for the tenant then has the option of taking live stock from farm to farm, and there is always a feeling of uncertainty about his affairs. If he falls into arrears we can keep no real check upon him, and if possible we avoid letting farms to men already holding land on other estates. Nor is this a matter only affecting the landlord's interest. A farmer with capital to invest may be tempted to hire more land simply from the cheap rate at which it can be had. If our advice were asked, we should certainly inquire if before looking for other holdings the farmer was really doing the best with that which he already had. To such a query the answer often proves unsatisfactory. In reply to our advice to put £5 an acre of more capital into a certain farm we were asked, "Where is the good of putting more money into land that only yields four quarters of Wheat per acre, with corn at such a low price?" We had actually to explain that the sole end and aim of such expenditure was to render the land more fertile, to improve the cultivation of it generally, and consequently to render it more productive. If only we could induce farmers to realise the possibilities of high culture, to see that a moderate area thoroughly well managed is far more profitable than a large one only half done, what a stumbling-block—what a hindrance to progress—should we remove, and how far more hopeful should we feel of the future of farming than we do now!

(To be continued.)

#### WORK ON THE HOME FARM.

As long as is possible without harm to the corn the hoes will be kept briskly at work among it where Thistles and Charlock abound. In some corn badly infested with Charlock we have resorted to pulling it out of the corn rows by hand. We have employed several extra boys and men at this work, for we are bound to do all we can to relieve the land of weeds. The Mangolds are growing freely, and the plants will soon be large enough for thinning. The horse hoes have been at work between the rows of Mangolds; Thistles, and in some parts Couch Grass, being abundant. Swedes have come well in moist soil, and the change to real summer weather will cause them to grow quickly away from the fly. Maize of the large Horse-tooth variety has been sown for the cows, bullocks and pigs. We strongly commend this summer crop to general notice for farmers who want an abundant yield of nutritious green food for live stock at the rate of 20 to 30 tons an acre. We have not yet tried Green Maize as an article of summer diet for sheep, but we have no reason to suppose they will not thrive upon it. Used in moderation it is useful for dairy cows, but they must not be fed with it alone, as it is then liable to impart an unpleasant flavour to the milk. There is still time to raise a crop, and it is certainly worthy of a trial. The land should be rich and in good cultivation in order to do full justice to the Maize plant, which is of rampant growth and requires plenty of food. Haymaking will soon be upon us, and we are having the mowing machines overhauled and put into good working order. Rakes and forks will all be examined, and due care taken that rick cloths, poles, pulleys, and ropes are all ready for the work. Haymaking is critical work, requiring close supervision and great care, then there is no reason why good hay should not be made. In point of fact good hay can always be made except, perhaps, in the extreme west, where rain is more prevalent than in other parts of the country. In a very wet district recourse can be had to the making of silage, but let hay be made wherever it is possible, as it affords us the option either of being used at the farm or being sold. Do not suffer any of the grass to ripen seed, but so arrange the mowing that the last of the grass shall be mowed before seed-ripening is possible. The ewes and lambs have finished the Rye Grass, and they have returned to the home farm to be folded upon Winter Tares by night and to run upon the grass in the park by day. Weaning has already begun, and we greatly regret to see old ewes

taken from the lambs and sent into the markets to be sold in wretched condition.

#### BATH AND WEST OF ENGLAND SHOW.

THE 109th Exhibition of this Society, held on the Durdham Down, Clifton, Bristol, was a decided success in every respect. Prior to the opening day much rain fell, and as a consequence the exceptional heavy traffic incidental to the collection of such an immense amount of heavy machinery, implements, and stock rendered the principal thoroughfares extremely unfit for traffic. With this exception, nothing was wanting to make a visit to the Show both interesting and instructive to the visitors who flocked to the grounds on each day the Show was open. The total entries in the live stock departments were 969, and of poultry there were 525 entries. About 40 acres of ground were enclosed, and of this agricultural implements occupied 4499 feet run; cattle foods, artificial manures, &c., 740 feet run; seeds 441 feet run; machinery in motion eighty-eight compartments, and open space for hay barns, greenhouses, &c., 2118 square yards, and miscellaneous exhibits 1470 feet run.

The show of shorthorns, eighty-three in all, was one of the best ever collected by the Society, and included remarkably well-developed animals in the several classes devoted to them. Fewer Devons were shown than anticipated, but there were several fine animals, and the heifers were well represented. The number of Herefords shown was seventy-four, and they were a good all-round lot. Guernseys were also well shown, and the Jerseys were a pretty lot, while the Sussex, though fewer in number than usual, comprised many fine beasts. Sheep of every description were well shown, though fewer in number than at Brighton last year, while the pigs in each class were considered exceptionally good, and the same may be said of the horses generally. Anything like a detailed account of the prizewinners, however, cannot be attempted, and it would require several pages to even briefly describe the numerous exhibits of machinery, implements, &c., all of which are now brought to great perfection, a fact evident enough to all observers visiting this great display.

The examples of ensilage made under varying conditions at Long Ashton, near Bristol, under the advice of Sir John B. Lawes, Bart., naturally attracted much attention from the innumerable agriculturists present, and much useful information must have been disseminated. The aroma arising from the sour "silage" was anything but agreeable, but this does not appear to deter the beasts from eating it readily, and should a wet season be experienced it is to be hoped that many farmers will adopt the system. At present the system is not much favoured in the west of England, where in many cases the farmers are scarcely so "go-ahead" as they ought to be.

A conspicuous exhibit was the grand stand or Royal Museum of seeds, roots, models, grasses, &c., erected by the Messrs. Sutton & Sons, the noted Reading firm of seedsmen. Those who have not previously seen similar exhibits by this and other firms were agreeably surprised at the artistic manner in which the various subjects are grouped, few thinking it possible to render immense heaps of Mangolds, Swedes, and other roots really attractive; while the numerous varieties of dried grasses, all legibly named, with large patches of beautifully green herbage, all serve to complete quite an attractive display. With a season like 1885 to contend with, extra fine samples of roots were scarcely to be expected, but there was no apparent falling off in the size and form either of the popular Sutton's Berkshire Prize Yellow Globe Mangold; Golden Tankard, yellow fleshed Mangold much in demand by the dairy farmers; Sutton's Yellow Intermediate Mangold, a favourite for shallow soils; or the exceptionally hardy Sutton's Champion Swede. In addition to these there was also a large collection of Potatoes, including all the good sorts distributed by this firm of late years.

Messrs. Webb & Sons, Wordsley, Stourbridge, also had a grand stand, this forming a good companion for that just noticed. In addition to extensive heaps of Webbs' Imperial Swede, a variety much in favour with exhibitors, and other equally as popular Swedes and Mangolds, they had a collection of finely grown Potatoes. Messrs. Webb had also sheaves of new kinds of Wheat, Barley, and Oats, as well as older kinds, of which they hold good stock. Grasses for all soils and purposes, including ensilage both dried and in a green state, were also extensively shown, and samples of various seeds, both for the garden and farm, occupied prominent positions on this large and well arranged stand. In addition, there were large groups of Tuberosus Begonias and Gloxinias, the strains being good in both instances.

#### REMARKS.

30th.—Very hazy till evening, then bright.  
31st.—Cloudy morn, fine bright afternoon, spots of rain in evening.  
1st.—Heavy rain about 10 A.M. with thunder and lightning; cloudy morning; lovely afternoon and evening.  
2nd.—Delightful morning, cloudy after 3 P.M., thunder at 3.50 P.M. and a little rain; fine evening.  
3rd.—Cloudy all day.  
4th.—Fine and bright, but cool.  
5th.—Fine day; thin haze in afternoon, with solar halo from 4 to 8 P.M.  
A fine week. Temperature near the average. The total rainfall this year already exceeds 12 inches.—G. J. SYMONS.

## PHENOMENA OF VARIATION, WITH SPECIAL REFERENCE TO FERNS.

[A paper read at the Horticultural Club, June 8th, by C. T. Drury, Esq., F.L.S.]

**I**N a paper which I had the honour of reading here last season upon certain newly discovered phenomena of reproduction in Ferns, I confined myself mainly to a description of the various normal and abnormal methods by which they are propagated, and an elucidation of the characteristic differences in these respects between the Filices and the flowering plants. With the view of opening a discussion of somewhat wider interest than the study of Ferns alone could do, I purpose to-night to dwell especially upon the peculiar faculty of variation possessed by Ferns, and the general character of such variation, in order to ascertain from the discussion which I hope will follow whether this faculty is displayed in as great a degree in the other branches of botany which may form the special study of my fellow members. I therefore start with the hypothesis that Ferns are endowed with a greater capacity of sudden variation under natural circumstances than other plants. I say under natural circumstances, because it is chiefly wild sports which I have in view, and not the wonderful differences which careful cultivation and selection are capable of effecting in almost every living thing if only time enough be granted.

The faculty of variation is general throughout organic life, but in the vast majority of cases the individual differences displayed between organisms of the same species are mainly the result of different conditions of growth, and do not involve any material alteration of structural plan. The offspring consequently present the same general appearance as the parent. Here and there, however, through some subtle occult influence, cases present themselves where the offspring is found to display strongly marked characteristics of which not a trace existed in either parent or, so far as can be ascertained, in any of its progenitors. These sudden departures from the normal type (or sports, as they are horticulturally termed) seem frequently to result from some accumulated influence induced by the artificial conditions attendant in cultivation. This is shown by the fact that many flowers under such treatment are liable after a certain time to vary suddenly either in themselves or their progeny, a fact to which we owe the immense number of strongly marked forms of floral beauty now existent.

In Ferns, however, under purely natural conditions—or, at any rate, under conditions as natural as we can obtain in a civilised country—there have been discovered an immense number of forms departing so widely from the normal types among which they were found, and which are so isolated in their occurrence and so entirely unaccompanied by any trace of intermediate aberration that we are forced to the conclusion that they are the direct offspring of spores from perfectly normal plants, notwithstanding which, they, in most

cases, truly transmit their peculiarities generation after generation to their offspring.

What an extraordinarily subtle influence must that be which in either plant or animal can so affect and transform the microscopic germ that the resulting offspring shall not only differ materially from the parent form, but possibly an altogether different type of structure, at once symmetrical and beautiful, shall originate, and be able to transmit henceforth its peculiarities to its offspring. Here, indeed, have we special creations, forming striking exceptions to the general rule of gradual evolution.

To return to my special theme—Ferns. Take for instance the Victoria Lady Fern, and grant the assumption, which cannot be avoided, that it originated from a normal plant. This normal plant we found to consist of fronds formed of a central stipe tapering to a point, and provided with side branches or pinnæ on the same plan and set on at an angle of about 30°; these being again divided on the same principle, the whole forming a feathery frond of lanceolate outline. On the back of every frond there are millions and millions of microscopic spores, which, during the indefinitely long life of the plant, are shed around and blown about in countless myriads year after year, not only from this plant but from thousands like it in the vicinity. Suddenly one, and apparently only one, of these spores yields a plant in which all the divisions, pinnæ, pinnules, and pinulets are not only duplicated but much narrowed and set at about right angles to each other. The outline of the frond is also greatly narrowed, and finally the tips of the pinnæ and the frond itself are many times divided, so as to form heavy tassels. Finally, it is abundantly sporiferous, and every spore is capable of reproducing its structural peculiarities; though, strange to say, the offspring are generally if not always easily distinguishable from the parents by a certain coarseness, the fine cutting of the ultimate division being, as it were, blurred and less sharply defined. On the other hand, I have raised hundreds of this form, and never saw a case of reversion to the normal form. This case of variation is an extreme type, involving as it does not merely a creting but also an essential variation in plan of structure, a combination of peculiarities which has so far not been discovered in connection with any other family of Ferns, though some few varieties are characterised occasionally by cruciate pinnæ. This Fern was found growing wild by the roadside in Scotland, and though the station was assiduously searched then and later no second example or intermediate form was or has since been discovered there or elsewhere. Another extreme form was A. F. f. *acrocladon*, found also by the roadside on a Yorkshire moor. Here the rachis and rachides possess such a tendency to division that the normal feathery nature of the frond is utterly lost, and the plant resembles a number of mossy balls crowning the much-divided stipes. Here, again, no intermediate form was found in the vicinity, and the necessary conclusion is that it originated at one jump, as it were, from the normal form. This case, however, is not so striking as that of A. F. f. *Victoriae*, since the ramification of the rachis is a comparatively common form of variation, and is only carried in this instance to an extreme extent. This again yields, I believe, fairly true progeny, in one of which the division is carried to such an extent that the whole plant resembles a ball of velvet.

This power of creting, in which the normally acute points of the rachis and rachides, of frond, pinnæ, and even of the pinnules become dilated and divided, seems common to all or nearly all of the British Ferns, only one or two species having failed so far to afford instances; and since, as I have said, the more marked departures have been found wild, it becomes a question whether exotic Ferns all over the world will not yield instances of the same phenomenon when sought for by an eye accustomed to the quest; for it is a peculiar fact that until the sight becomes habituated to the search for special features the eye unconsciously is liable to overlook and pass

by the most striking characteristics. Hence a botanist whose specialty is the discovery of new species only would readily detect an altogether new plant, but fail to note that one amongst a crowd of familiar plants possessed unusual features. As an instance of this, I recollect once hunting over a lot of *Scolopendriums* with a good general botanist, and I found no less than seventeen *ramose* and otherwise abnormal plants among them before he found one, yet in his own element he would point out an uncommon flower on the other side of a field where I could hardly discern a plant at all. To this may be attributed the fact that so few abnormal exotics, and especially tropical Ferns, have been found, though I venture to think the quest is worth while; for let the scientist term them monstrosities if he will, I contend that in many cases the abnormal forms infinitely transcend the normal ones in beauty,<sup>†</sup> while admitting freely that, on the other hand, many are far more curious than beautiful. Anyone who has seen a grand specimen of *Lastrea cristata*, our nearest approach to a Tree Fern, and splendidly tasselled, must admit that such a cresting on *Dicksonia antarctica* or a fine *Cyathea dealbata* would be simply magnificent, and I am sure that somewhere in the untravelled habitats of these Ferns their crested forms are quietly awaiting their discoverer.

In connection with this power of crestation I would ask, What is the parallel phenomenon in flowering plants? Hardly, I think, the doubling of the flowers, though that suggests itself as a near approach; yet from the fact that the sterility which is usually attendant upon such doubling is associated in the Ferns with the plumose and not the crested varieties, I think the connection should be looked for there; the extremely foliose character of such forms seeming to absorb all the vigour of the plant, so that spores are either altogether or almost absent, precisely as the multiplication of the flower petals seems to affect the seed producing parts of the flower. This idea I only throw out for discussion.

Here again the most marked instances of variation in the plumose direction have been wild finds. Dr. Wills's *Scolopendrium crispum*, for instance, has deeply curled fronds of normal strap-shaped outline, but much wider—over 4 inches in some cases. The Axminster and Horsfall plumose *Athyria* were also found wild: and to cut this part of my paper short, so were the greater part of the abnormal forms in cultivation; though, thanks to the selection of some of our careful cultivators, such as Col. Jones of Clifton and others, the offspring of such finds have been found to develop their characteristic beauties to a far greater extent than the parents, some of Col. Jones's *Polystichums* especially, the result of selection and hybridisation being apparently the ne plus ultra of feathery delicacy.

I have alluded several times to the constancy of such variations, but there are some curious exceptions to this rule, as every Fern-hunter knows to his cost. Many of the most marked and beautiful forms yield common progeny, and also are apt to "sulk" as it is termed, and refuse to produce anything but normal fronds unless grown exactly as they like it. One of my own best finds affords the most remarkable instance of this instability that I know of. In 1884 while in Scotland I found near Kilmarnock a really splendid form of *Lastrea Filix-mas polydactyla*; in fact the most polydactylous form by far which had been seen. The plant had five or six huge fronds, all with beautifully pendulous pinnæ tasselled with as many as twenty divisions. I brought it to London and displayed it with great pride to some of the best judges, who one and all decided that it was a thoroughbred beauty, as it was profusely covered with spores. I carefully gathered some from the best parts of the frond and sowed them. The plant being deciduous the foliage disappeared in the winter, and the following season I watched the rising crown in confident anticipation of a finer and more symmetrical plant than the removal and travelling had per-

mitted it to be the previous season. Judge, then, of my disgust when a common *Filix-mas* was slowly developed without even the simple merit of the normal form, for many of the pinnæ were deformed and depauperate. Later on a frond or two arose with faint signs of division on the apices of the pinnæ; meanwhile the young ones began to arise from the spores, one and all common Male Ferns. Another exactly similar plant found at the same place, but some 20 yards distant, in the succeeding week by a cousin of mine, showed slightly crested pinnæ here and there, and that was all—verdict, a rogue. Still I would not despair, and though this year perhaps it might get over its sulkiness, the spring comes, and slowly rises the shuttlecock-like circle of fronds, all common again except a few deformities; then an odd frond rises, pinnæ slightly crested, then another, and ho! it is heavily tasselled and as beautiful as could be desired.

Meanwhile the seedlings have been developing fronds 4 to 6 inches high, all common with the exception of two, which in the prothallus stage it had transferred to a *Todea superba* frame, these two heavily tasselled from the beginning. I wait a little, and behold here and there generally there are fronds arising among the seedlings which promise not only to equal the parent at its best but even to surpass it. Here is inconstancy with a vengeance, but by no means one of the worst cases, for many a presumed good find has reverted altogether when removed from its birthplace, never displaying its peculiarities again.

That this capacity of sudden variation is not always confined to a single spore is evidenced by the fact that under cultivation instances have been known where a number of exactly similar plants have appeared which have been extremely different from the parent. I have a very dwarf and congested form of *Blechnum Spicant* raised from *B. S. strictum* of Barnes, of which I am informed by the raiser fifteen plants made their appearance, yet no one would credit the parent with such offspring unless on the very best evidence. A still more remarkable case occurred some short time back amongst my own sowings. I sowed spores from a very finely cut form of plumose *Athyrium* (*A. F.-f. plumosum elegans*, *Parsons*) of purely normal outline, yet among a large batch of plants only one resembled the parent; the whole of the rest were heavily crested on tips of frond and pinnæ, most of them symmetrically, but some were irregular. As the sowing was a very special and unmixed one and duly registered, and as, moreover, I have never sowed spores from a plant similar to the resulting ones, I am quite sure of their origin. They all, moreover, possess the plumose character of the parent.

It is a well-known fact that Ferns otherwise normal develop occasionally some local eccentricity which is liable to affect the spores borne in its immediate vicinity. There is, for instance, a very finely crested *Gymnogramma* (*G. Lauchena grandiceps*) raised by Dixon of Hackney, some years ago, and the raiser informed me that upon an ordinary plant of *G. Lauchena* he noticed the tip of one of the pinnæ merely dilated, and as it bore some sori he sowed it, the result being a house full of densely crested plants. It has, therefore, suggested itself to me that many of the varieties found may originate in a similar way, though this of course does not detract one iota from the singular transformation of the germ which must precede the appearance of the transformed plant. It is also manifest from the case of the plumose *Athyrium* just described that the abnormality is by no means necessarily visibly shown in the parent. The most common form of variation is that of crestation, varying from merely division of the tip of the frond to an indefinite ramification of parts forming a ball like *Athyrium F.-f. acrocladon*. The other forms are enumerated, but may be roughly classed under the following heads—Depauperation, the extreme form of which is the reduction of the plants to mere midribs: Dwarfing, implying merely reduction in size: Congestion, where the spaces between the divisions are so reduced that the parts more or less densely overlap and crowd each other:

<sup>†</sup> Compare the normal *Athyrium* with the best *plumosum*, and the difference is as great as between a common goose feather and that of an ostrich.

Plumation, which is generally accompanied by partial or entire absence of spores, and which consist in a greater foliaceous development, apparently produced at the expense of the spores. Several of these classified eccentricities may be conjoined in one and the same plant, as, for instance, in *L. F.-m. angustata cristata congesta*, where the ordinary lanceolate frond of the Male Fern is narrowed to about an inch in width, is extremely congested and finally crested, this being, I believe, the result of three separate sports; first a natural wild sport—viz., the crested but otherwise normal form, a spore of which gave a narrowed form from which, I believe (though I have not its history), the congested form was raised. Besides these classified forms of varieties there are hundreds which can only be ranked as oddities; such as, for instance, the cornute forms which have arisen in several families, where the midrib is suddenly extended from the surface of the frond, like a Thorn; the proliferous forms, where young plants bud out in the most unexpected places; the serpentine forms, where the ordinary shuttlecock shape is resolved into a sort of Medusa's head, each frond coiling away from the crown and twirling about like a snake. Mr. G. B. Wollaston has a *Polystichum* answering this description exactly. Then there are the marginate forms, where regular ridges are developed on either side of the frond; pociiform and truncate varieties, where the frond suddenly stops and develops a pocket, and so on *ad libitum*.

With regard to proliferation, I should like here to record the fact that in my collection I have recently found a seedling *Lastrea dilatata* bearing a young plant on the first frond evolved from the prothallus. A plant of *Asplenium Adiantum nigrum* var. *microdon* has developed a young plant in the axil of one of the pinnæ. So far as I know proliferation has not been recorded in connection with either of these species.

Having drawn your attention thus to the main forms of variation to which Ferns are subject, and some of the peculiarities attending their occurrence, I will reserve further observations on the subject until after the discussion.

### AMMONIA IN VINERIES.

I FEEL sure Mr. Iggulden has been somewhat disappointed that some other of your able correspondents have not taken up this subject in reply to his valuable and interesting article which appeared in the *Journal* for April 22nd of the present year. For my part I have been eagerly looking for some of our great fruit-growers to give us their experience, but not a word has appeared. Why is this? Is it because the subject is considered of no importance, or is it not sufficiently understood? I am inclined to think the latter is the cause; for although we occasionally see an article devoted to the subject, it never seems to enter the minds of gardeners generally to put the idea into practice. This, I think, is to be regretted; for I am convinced that an ammonia-charged atmosphere is of the greatest benefit in vineries if applied at the proper time and in moderation.

Having been asked to give my experience I will now endeavour to describe how it occurred to me that ammonia was so beneficial to the growth of Vines; but before doing so allow me to remark that I am a young gardener, and feel myself incapable of doing justice to the subject, but I write to gain knowledge, and should I say anything that may be at variance with the views of abler and more experienced men I shall esteem it a favour to be corrected.

In the year 1877 I was placed in a responsible position through the illness and death of my father, who was a thorough hardworking gardener, and one of the old school. Amongst other things I had three vineries under my charge, and was expected to keep up a supply of Grapes from June till February. This, under favourable circumstances, would have been an easy matter; but the Vines were very old, and the houses badly heated, and so constructed that it was impossible to give front ventilation, except through the brick holes in the front wall where the stems of the Vines came through, they being planted in an outside border. Now it so happened that the middle Vine in the early house had been planted deeper, and came through the wall quite 18 inches lower than the rest. For this Vine a narrow inside border had been made, the soil it contained being supported on one side by the front wall, on the other by a brick flue.

During the time the Vines were making growth this small border was kept constantly mulched with fresh horse droppings for the purpose of supplying rich food to the roots, not a thought being given to the ammonia that was arising from the manure and feeding the foliage above; but that such was the case I have not the slightest doubt, for one day while working in the house I was struck by the appearance of the leaves immediately over this border. They were of a much deeper green, and possessed such a thick leathery substance, quite unlike those in any other part of the house. Just before this I had read an article in the *Journal*, I think from the pen of Mr. Luckhurst, which led me to believe it was the ammonia these Vine leaves were inhaling that caused this healthy appearance; and ever since that time I have been quietly following the practice of applying ammonia in the form of liquid manure in all vineries under my charge, and I am happy to say without a single failure or accident.

When I came to my present situation a year ago I found the Vines in an unsatisfactory condition, but being myself very fond of Grape-growing I was not long in setting to work to improve them. The first thing done was to apply a dressing of soot to the borders, and then thoroughly wash it in, for it was plain to me the Vines were being starved; the leaves were small, and of that thin transparent nature which tells its own tale. Moreover, the laterals were much too numerous, in some instances there being as many as five on a spur, and the rods not more than 18 inches apart. How, I ask, was it possible to produce satisfactory Grapes under these conditions?

As soon as the fruit was off we commenced thinning the growths, so as to let in all the light and air possible. Then the borders were looked to, and we found a quantity of roots within a foot of the surface; but they appeared to have no feeding ground, for instead of branching out in all directions they ran through the border like whip thongs. These roots, after being notched at different places with a sharp knife, were laid in a fresh compost, consisting of turfy loam, earth-closet manure, lime rubble, and soot. This being done, the borders, which are inside, received another watering, and about the end of November a good covering of dry Oak leaves was put on, making all safe for the winter.

Very early Grapes not being required, the Vines were not started this season till February, and now comes this important ammonia business again. To induce the Vines to break strongly 3 gallons of liquid manure was sprinkled over the floors and stages of the house twice a week. This had the desired effect, for the Vines broke evenly and fairly strong. The use of the liquid manure was then discontinued till after the Grapes were thinned, then the same quantity was applied every alternate day. I ought to mention that this was done at closing time, when the atmosphere was charged with moisture, there being then much less fear of injury. Now that the Grapes are stoned ammonia is given every day. It may be asked, "What about the smell attending this?" My answer is that I have never had a single complaint respecting its use, and those of your readers who have never tried it would be amazed at the rapid way in which the smell passes off. It will be observed that we apply a small quantity, and that often, and that the Vines enjoy it there is not the slightest doubt, for the improvement in their condition in so short a time is marvellous.

In conclusion I wish to thank Mr. Iggulden for what he has said on the above subject, and he will be glad to know that his teaching is appreciated by—F. H. W.

### LIVERPOOL—VISITORS' GUIDE.

By whatever route Liverpool is approached visitors will not be favourably impressed with the locality as one suitable for gardening operations. The prospects only a few miles out are by no means encouraging, for tall chimneys and factories are abundant. In spite, however, of these and other difficulties visitors will find gardening well done. Liverpool gardeners have long since boasted that they are capable of holding their own, and I think after the neighbourhood has been visited it will be readily admitted that they have good grounds for such an assertion. It is perfectly true that Liverpool cannot boast of having within her suburbs so many lordly establishments as crowd the neighbourhood of some great cities; but there are perhaps more moderate-sized gardens where good culture is carried out than are to be found within the suburbs of any other city. It is not always in the largest establishments that the best gardening is to be found; on the contrary, the reverse is often the case. It is generally from such gardens as these that the plants and fruits are staged at our spring, summer, and autumn exhibitions. These certainly are exceptions to this rule.

It is my intention to name only those gardens that are not a wide distance from the centre of Liverpool, and which are readily reached by rail or 'bus. It is certain that gardeners will not have the time to pay a visit to the whole of the establishments within a certain radius, and therefore many that are equally well worthy of a visit will naturally have to be left

out of this guide, not because they are less interesting than others that will be named, but because they entail a certain amount of walking, which means loss of time. Gardeners generally have walking enough at home, and consequently they require as little as possible when they are out. I propose grouping the gardens to be visited as much as possible, so that the same ground will not have to be travelled over twice.

The botanic garden joins Wavortree Park, in which the Exhibition is to be held; in fact one or more of the tents as well as a band of musicians will be within the garden. The neighbourhood of the garden is a very bad one, and a worse for gardening purposes could scarcely be found. This was not the case formerly, but now it appears to be within the city, for nothing but bricks and mortar surround it. Gardening, however, is very well done, all these drawbacks considered, and great credit is due to Mr. Richardson, the able curator, and his foreman, Mr. Powell. A splendid idea of what will do in the neighbourhood of a town and what can really be done may be gained, and I advise gardeners to supply themselves with a note-book and pencil, for a few notes of what are thriving may prove of service to them some day, for gardeners never know whether they will be called upon to practise in the vicinity of a town or in the pure air of the country. There is a good collection of herbaceous plants, and plants suitable for furnishing walls. The glass arrangements are also extensive, and the various departments contain some noble specimens. The private houses at the back are an interesting feature of the gardens, and Mr. Richardson will be only too pleased to allow any gardener to inspect these as well as those daily open to the public. The bedding has generally been well done in these gardens, but the season has been much against this portion of the garden decoration, for there is not a sufficiency of frames for the accommodation of the enormous quantity of plants required. Another drawback to the beauty of the establishment is the large numbers of plants that have to be taken out in all weathers for the decoration of the Town Hall and other public buildings. Two Royal visits in a season have made hundreds of plants look seedy, in addition to the large quantities that are only fit for the rubbish heap after they return home from being used in ball-rooms and other positions. The houses could be kept far more attractive if this work could be dispensed with. It may here be stated that Mr. Richardson not only superintends the Botanic Garden, but all the parks and squares come under his charge.

To pass from the Park, the nurseries of Messrs. T. Davies & Co., Wavertree, may be inspected while at the Exhibition or Shipperies. These are reached by taking a tram (for 2d.) from the point where passengers alight for the "Royal Show." Some of the Wavertree trams pass through the main street of the village, and in less than ten minutes from this point the nurseries alluded to can be reached. They are on the right-hand side. There is a large extent of glass, and plants generally are well done both inside and out. Elm Hall, Wavertree, is not very distant and should be visited, for Mr. Cox, who presides over the gardens, is certain to have something at home worth seeing, although he may have many of his best plants at the Show if he succeeds in getting them into form by that date. Mr. Cox is the rising successful exhibitor in this neighbourhood, and if I judge rightly he will well fill in a year or two the premier position rendered vacant by Mr. Wm. Mease. In the past Mr. Cox has been most successful at the shows held by the Liverpool Horticultural Association, and in the future I predict he will be more successful still. I strongly advise gardeners wishing to see Elm Hall to inquire at the nurseries of Messrs. T. Davies & Co. the best route; it can be pointed out to them better than I can detail it here.

From Wavertree station, on the London and North-Western Railway, the train can be taken for Mossley Hill; it is the next or second station from Wavertree, the station being close against Messrs. Davies' nursery. The same place (Mossley Hill) can be reached from Edge Hill station, which has been described, or Lime Street station, if the train is taken from the city. At Mossley Hill turn to the left out of the station and go straight forward for some distance, when the first turning to the right should be taken, which will lead to Wyncote, Allerton, the gardens of C. W. Newman, Esq., where Mr. W. Mease has so successfully practised for many years. These gardens are not what may be termed extensive, but they are well kept, and every portion of ground turned to good account. I may say a little of everything is grown, and all that is taken in hand is well done. No visitor to Liverpool should pass these gardens without paying Mr. Mease a visit. From Wyncote Calderstone can be seen. It is only a few hundred yards away, and a very pleasant half-hour may be spent with Mr. W. Tunnington, who probably knows more about Chrysanthemums than any other man about the neighbourhood. Pines, stove, and greenhouse plants are also well grown at Calderstone.

These visited, the ground must be retraced to Mossley Hill station for Garston Dock station, or the distance to Garston may be walked. While walking to the former station the latter could be reached, and a visit paid to the Garston Vineyard. Garston can be reached either from the central station or from Lime Street. The former route will be referred to again. The Vineyard is easily found when Garston is reached, and anyone will point out the road. The nurseries are about fifteen minutes walk from either of the stations. A whole village of glass will be found in these nurseries, filled with all kinds of flowering and foliage decorative plants to meet the demands of Liverpool for plants and cut flowers. Young Vines and Tea Roses are also largely grown. Orchids, in all stages of development, fill a score or more of houses. The large Madresfield Court Vine which has been written about so many times, fills two large houses if it has not been recently destroyed, which I do not think is the case. Young Ferns are also a speciality. From this point a return to town can be taken from either station, or Woolton and West Derby may be reached from the

Cheshire Lines Committee station at Garston. At both of the places named visitors should break their journey, for there are gardens at both worth seeing. But I shall give this route from the city, starting from the central station, for there are several places of interest that can be reached from this company's lines.

One of two routes can be selected for the purpose we have in view—namely, the train from the station named or by the Prince's Park 'bus, which passes the Washington Hotel in Lime Street. I advise the 'bus, although it takes a little longer, but this will give strangers an opportunity of seeing another portion of the town, and Prince's Road is well worth seeing, towards the end of which a boulevard has been formed. The trees are young, but it certainly reminds one somewhat of the Continent. By this bus Prince's Park can be visited, for passengers can alight close to it. This is not a large park, but it is well laid out, generally some good bedding in it, but the date is too early to see this in its best; nevertheless, it is well worth inspecting. Mr. Mason presides over this park, and the management reflects great credit upon him. A few minutes from this park Sefton Park can be entered. I may here state that from the central station a ticket should be taken for Mersey Road station, the nearest for Sefton Park. By this route it could be passed through to arrive at the point we wish to get at presently. Sefton Park should be inspected, for it is by far the finest in Liverpool. It reminds one very much of Battersea Park, London, but has no bedding. It is beautifully laid out with its broad well-kept roads and winding walks and ornamental rockwork and lake. There is also a very fine collection of ornamental forest trees and deciduous flowering trees and shrubs. Those interested in landscape gardening—and we all are, or should be—should not visit the city without thoroughly inspecting this large beautiful Park.

From this Park can be seen the drive gates of Otterspool, the residence of Sir T. E. Moss, Bart., where the late Mr. Wm. Hinds lived and wrote for many years. Mr. D. Lindsay succeeded Mr. Hinds, and still has the charge of the grounds, which have steadily improved. The drive alone is worth a visit, without mentioning the glass and other portions of the grounds. Those who travel from town to Otterspool station, the one following Mersey Road, on the same line, enter from the station by a small gate, but by this route the drive is missed, which is perhaps the best feature of this place, as far as the grounds are concerned. From the gardens at various points a splendid view of the Mersey is obtained; in fact, it washes the outer edge of the garden, and sometimes carries some portion away with its rushing mighty current. But I am not going to describe this or any of the gardens I intend naming, for I shall only, by so doing, destroy the pleasure of those who visit them.

The train this time must be taken from Otterspool to Cressington, which is the next station. From here the nurseries of Messrs. R. P. Ker and Sons, Aigburth, are reached; they are situated about four minutes walk from the station. This is the home for Crotons. The Croton house is now very handsome. I daresay some of the best plants will find their way to the Show; they certainly ought to do so, for they are wonderfully fine; however, if they do a good number will remain behind that will be worth inspecting. Cyclamens are well and largely grown, also Dracenas—in fact, a general collection of stove and greenhouse plants. It is in good order outside, and the collections of trees and shrubs are large. Gardeners when in this neighbourhood should pay it a visit.—A CITY MAN.

(To be continued.)

## FRUIT STONING.

(Continued from page 459.)

THEN soil exerts a great influence on fruit stoning. Calcareous matter seems essential, and few fruit borders are made without an addition of lime rubble. I have known instances of Cherries falling year after year being rendered fruitful by the addition of a 6-inch thickness of lime rubbish mixed with the top 2 feet of soil, the roots being lifted to within a yard of the stem and laid in the fresh material. This on a peaty loam on the lias formation. There are no doubt soils that contain sufficient lime without any additions, but there are many soils that contain so little lime as to render an addition of lime absolutely essential to a satisfactory crop of fruit. In fact, all soils not calcareous should have addition of not less than a tenth of lime rubble or chalk, and in soils that are of an alluvial or peaty nature a sixth is not too much. In all cases it should be well mixed with the soil to a depth of 2 feet, and if drainage be necessary it may form the upper layer of that in the case of all fruit borders, particularly in the case of Figs, Vines, Peaches, and Nectarines and Cherries. It does not seem so necessary for Pears, Apples, and bush fruit, but for all stone fruits is a necessity of successful practice. Apricots and Plums can hardly be grown without lime, and Cucumbers and Melons are healthier and not so liable to gum, gangrene, and other ills when lime forms a component part of the compost. In some cases I have used as much as a sixth for mixing with the loam for both Cucumbers and Melons, and had some disasters through using lime of the magnesian character as prevails in some parts of Yorkshire. The magnesian limestone may not do much harm on peaty soils, but its causticity remains so long that it must be

used with care. I also found it deleterious to Strawberries and even Gooseberries through using it in perhaps excessive quantities. The quantity used were in excess of a bushel per rod, and yet this quantity acted beneficially on Vine and Peach borders, nor were the effects other than advantageous in the case of Apricots, Plums, and Cherries. I cannot say the same of Pears and Apples; they seemed deteriorated by additions of caustic lime, and contrariwise affected by additions of old mortar rubbish. For all fruit trees that do not stone or even set well I advise a bushel of freshly slaked lime to be applied per rod in the early autumn or spring in dry weather, and point it in as deeply as the roots will allow. Lime has a tendency to sink into the soil, but there is no harm in burying the first applications rather deeply, as the after dressings can be given nearer the surface. These lime dressings may be given every year the first three years, and every other afterwards for a decade, which is as long as I have experience with the same Vines or Peach trees. Figs will take even more, but Figs like it best in the old mortar state, and so do Cucumbers and Melons. Fruit borders from the rich surface dressings and applications of liquid manure contain much humus, and there can hardly be any deficiency of potash, and it may be urged of soda and lime, as the liquid and dung of animals contain those, especially potash, in the urine, yet a dressing of potash has been found beneficial, but I find a peck per rod is sufficient to give of wood ashes, and even less for Peaches. Apricots, Plums, and Cherries have the growth too much accelerated by potash, and the reaction is not reassuring; indeed the action of potash seems to be highly favourable for a time, and then leaves the trees in a worse plight than before its application. Lime, on the other hand, is of great permanence, and it is essential to Figs and Grapes as well as all stone fruit. We can of course get all we want out of liquid manure and decayed leaves, and in the case of Figs and Vines in pots with the run of fermenting beds, but for permanent borders lime is an essential of fruit-forming matter, and necessary to the health and stability of the trees.

Silica is by some means rendered soluble, as it is absorbed, at least enters into the composition of plants, and especially of the stone as well as stems, and is particularly valuable in the growth of Figs, Vines, and Cherries, and Melons never have as much solidity in an aluminous soil as in one of a gritty description. Grit, therefore, in soils deficient of sand should form a component part in the formation of fruit tree borders, particularly for Figs, Vines, and Cherries, a sixth of road scrapings being a suitable quantity for Figs and Cherries; and for Vines, as the soil is usually of a light nature a lesser quantity, or a tenth, will probably suffice. Through lack of inorganic substances failures in fruit stoning and finishing not infrequently arise.

Culturally stoning is a process that requires time and steady supplies of nutriment. If we hurry Vines we get small berries and an indifferent finish; if we force Peaches we bring the fruit down about our ears, and if we will have Figs earlier than usual we must not seek it by forcing hard when the fruit for the purpose of perfecting its seed is stationary, but commence forcing earlier, so as to allow time for the performance of Nature's work. There must be no check—a close vitiated atmosphere one time, and a current of cold air rushing through the house the next, a soddened soil one time, and the roots lacking moisture another, and no encouraging of growth that will necessitate large reductions of foliage at a time; but the temperature must be steady, without great fluctuations or depressions, regularity in the supplies of moisture and nutriment, and a steady progressive growth insured and maintained.

To insure stoning we must avoid overcropping, thinning early and gradually so as to give no glut of nutriment by an excessive thinning, but steadily divert the liberated nutrition into fresh channels, imperceptibly rather than by impulse, and so apportion the crop that we not only effect a satisfactory stoning, but obtain good flesh surrounding a well developed seed. A perfect stone or seed and perfection of flesh, finish, and flavour are inseparable. Ripe wood will stone more fruit than wood not near as ripe; indeed we get more fruit to stone on a branch as thick as a quill than on one as thick as the finger, length for length, but the one is nearly all stone, and the other is marked by a vast proportion of flesh.—G. ABBEY.

#### FINE-FOLIAGED PERENNIALS.

It might be reasonably assumed that we have among hardy perennials as fair a proportion of plants with handsome and ornamental foliage as among those which require the temperature of stove structures, and though the former may perhaps be of a somewhat different aspect, I think it highly probable that in many cases the plants are not sufficiently known, otherwise they would be brought into more general use. There are

hundreds of gardens where the majority of our fine-foliage perennials might be brought into use, and especially those gardens which have a naturally picturesque appearance. Another reason, perhaps, why these plants are not so popular as the fine-foliage plants of our stoves, is that they do not receive the encouragement at our horticultural exhibitions that their merits entitle them to. It not unfrequently happens that large and elaborate rockeries are devoid of vegetation to such an extent as to render the huge stones unseemly and unnatural, whereas by employing some of the plants I shall hereafter name, the whole might be in perfect harmony. Then, again, for isolated positions on the lawn, for damp shady spots, or for the margins of lakes or streams, there are numbers of these plants which would be perfectly happy, and at the same time assist in relieving some previously monotonous outline. One instance more—in a fernery, in some shady grove, or arranged as often is the case on large sloping banks beneath the shade of trees, there is room for some of the more stately Bamboos or Grasses—anything, in fact, that would delight in shade and improve the general appearance of the whole, and who would object in such a spot to see Orchises appear in the spring time, or Lilies during the summer and autumn?

The first genus is the *Acanthus* or Bear's Breech, in which we have many very fine plants. Taken collectively, the group is remarkable for its stateliness, and for their large coriaceous, and, in some species, shiny foliage. The leaves are beautifully recurved, and the singular flower spikes rising to a height of 3 feet, give to the whole a highly graceful and ornamental bearing. All are hardy, and are best suited for isolated positions on the lawn, high up the large rockery, or for the large border. The most distinct are *longifolius*, *latifolius*, *hybridus*, and *spinosissimus*.

We next find in *Bocconia cordata* one of the most handsome among perennials. It rises to a height of about 8 feet or thereabouts, and is admirably adapted for positions on the lawn or for shrubberies. Towards the latter part of the summer it produces terminal panicles of peculiar brownish flowers. It is self-supporting, and makes a most handsome bush, and it may be well to observe it is deciduous. The two genera to which I have referred to are both of easy culture, the former being reproduced from seeds, or from root cuttings, and by division. The latter makes a quantity of stoloniferous growths, and is in consequence of simple culture.

The next plant to come under notice is somewhat rare, especially in anything like large clumps. This is *Cimicifuga racemosa*, as conspicuous and handsome in its long drooping racemes of white feathery-like flowers as it is in its large biternate deeply cut leaves. This lasts in flower for some considerable time, and grows about 4 feet high; the finest specimen I have seen being about the same through. Specimens of this size, however, are extremely rare; still it is of such sterling worth that it should receive every encouragement. It prefers a rich loamy soil and plenty of moisture during the growing and flowering season.

Another genus which contributes species with conspicuous foliage is *Echinops*, all of which are adapted for naturalising, singularly curious being the large globular heads of blue, purple, and white flowers; and following this we find *Eryngiums*, which somewhat resemble the former group, at least in some of the species. The latter prefer situations high and dry, for not infrequently do we find them more severely injured in excessively wet winters than in winters which, like the present, have been attended with more than the usual frost. This group is also known by the popular name of Sea Holly, which no doubt it received from its densely spiny leaves. They thrive remarkably well near the seacoast, and are, therefore, suitable ornaments in seaside gardens. They differ somewhat in the habit of growth, *E. amethystinum* being perhaps the most hardy in general. It is truly a handsome plant, and usually attains a height of 3 feet. The leaves are covered with sharp spines, the flower heads and bracts being of a pleasing blue. *E. pandanifolium* hath entire leaves exceedingly spiny at the margins, and of semi-erect habit of growth, from the centre of which the flower stems issue, attaining under favourable conditions 8 feet and even 10 feet high, with branching heads of reddish flowers. It is when seen thus that it claims a first position among ornamental plants; and then we have quite a distinct species in *E. serra*, with broadly lanceolate spiny leaves 2 feet to 3 feet long, nearly prostrate. This is a conspicuous plant for the large rockery, and quite distinct from any other species I know. Others differing from those named are *E. alpinum* and *E. maritimum*, the latter being the plant usually known as the Sea Holly.

The Plantain Lilies or Funkias include some handsome species. All are hardy, and delight in deep rich loam, being allowed to remain undisturbed for years if effect is needed. To give those unacquainted with their beauty some idea of these plants I cannot do better than compare them, and especially the green-leaved kinds, to *Eucharis Sanderiana*, for there is a strong likeness in the foliage of the two plants. Those who know the latter may form some idea of the value of the Funkias as decorative plants by extending their ideas to specimens 3 feet across, which the larger kinds often attain. Some of the best are *Fortunei* and the golden-leaved form *Fortunei aurea*; *Sieboldi* and its variety *aurea marmorata*; *subcordata grandiflora*, which is uncommonly like *Eurycles australasica* in foliage, and not only a valuable plant for ornamentation, but equally so for its flowers, which in a cut state are very serviceable. For the greenhouse it has comparatively few rivals either in beauty or its delightfully fragrant flowers; and, further, I may add that established plants in pots force readily. Thus we have a group of plants truly noble in aspect and highly valuable as flowering plants. There are many other forms smaller in foliage and suited for pot culture for conservatory decoration, but which I will not allude to now.

*Gunnera scabra* and *G. manicata* are giants, and rejoice in abundant supplies of moisture in summer time, and in winter must be kept comparatively dry. Moisture seems the one thing needful to the free and full development of these plants, though I remember one particular instance of a giant specimen of *G. scabra* planted in light sandy soil of only moderate depth, situate on a deep bed of gravel. In winter this plant was protected by a deep covering of bracken and its own giant leaves, and each summer attained a diameter of 12 feet or more, the individual leaves being 4 feet to 5 feet across. It is a plant of giant proportions, and suited for isolated positions on the lawn and in moist shady positions, as it comes from the deep shady ravines of the Andes. Not less gigantic is *G. manicata*, both species being as remarkable in their immense columnar spikes of flowers as in their unique foliage.

In *Helianthus orgyalis* we have the most graceful of its genus. It attains 8 feet or 10 feet high, the stems being thickly furnished with linear lanceolate gracefully recurved leaves. Its flowers, however, are very small, and to this fact may be traced its somewhat sparse distribution. It is, nevertheless, a very distinct and pleasing plant for the large border, for the shrubbery, or for positions on the lawn.

The Cow Parsnip or *Heracleum* have been called the giants of Siberian vegetation, and while probably too coarse for the lawn or the border it is admirably adapted for naturalising in woodlands or semi-wild places, or here and there in large shrubberies. *H. giganteum* is, perhaps, the finest of the genus, growing about 12 feet high and having immense heads of white flowers, and is remarkable for its free growth and development.

We have next a very fine plant in *Senecio japonicus*, also known as *Erythrochaeta palmatifida*. It is quite distinct from all else and grows about 4 feet high, with large distinctly palmate leaves on petioles 3 feet in length, and having lax panicles of golden yellow flowers. The Goat's-beard *Spiraea*, *S. aruncus*, is likewise a very ornamental plant in foliage and flower, the latter composed of innumerable small white flowers in long feathery plumes. It delights in abundant moisture. And to conclude the list of these useful decorative plants I may mention *Symphytum officinale variegatum*, which forms handsome tufts of beautifully variegated leaves. Its flowers are of but little moment, but which is fully compensated for in the rich golden which its leaves assume in spring, and which it retains throughout the summer. Such, then, are a few of these useful subjects which I am sure would find many more admirers than they do now, provided they were brought more to the front so that their beauty may be fully realised.—J. H. E.

### RUSHING INTO PRINT.

UNDER this heading you have permitted "Head Gardener," in your last issue, to make allusions to me in connection with the premium case and the gardener concerned in it. Of the latter it is said that his "identity may be guessed by many." Most likely it will if his actions are reflected in what I and others have written, but not otherwise, and as far as I am concerned not half a dozen persons are wiser than they were before anything was written respecting him. I did not even supply the Editor of the Journal with his name. Your correspondent does not admire my conduct in the affair, neither do I admire unjust or mean actions, and to publicly denounce them can have no terror but to evil doers. My motto has been, "Do to others as you would like to be done by." Your correspondent's objection of the steps I took in this matter leads me to state that judging from the gusto with which he has related what seems to be a paltry incident that occurred twenty years ago, and if true it appears injured no one, he would not hesitate to "pillory" anyone he thought fit.—W. P. R.

[According to our correspondent's standard of probity "Head Gardener" was justified in relating the peculiar "incident" referred to, and which is described on page 419. It is quite true that "W. P. R." did not, as he ought to have done, supply us with the name of the gardener whose action he criticised, though it was known to us before we published his letter, neither did he supply the name of the young man on whose behalf he wrote, and thus relieve us of the necessity of obtaining it from another source. On the question of premiums generally, we fail to see what a gardener has to gain by discharging a young man who performs his duties satisfactorily, and who is at the same time willing to meet his obligations.]

## CHRYSANTHEMUMS AND THEIR CULTURE.

(Continued from page 461.)

### FIRST BREAK.

THERE is no exact time when the plants make their first break, as so much depends upon various causes—viz., variety, time the plants were struck, and the locality in which they are grown; all these tend to alter the date of the "first break." If the plants were rooted about the time advised many will show their first flower during the early part of May and others early in June. Many plants are spoilt at this stage of their growth through want of attention, or in some instances a lack of knowledge to know how to treat them at this important period. The "first break" is caused by the formation of a flower bud in the point of the young growing stem, this bud causes other branches to start from the axils of the leaves below the point where the flower bud formed. On plants of some varieties as many as ten additional growths will

spring from the one stem, and a lesser number from other varieties. These would all in due time grow and produce flowers, but the object of growing the plants to produce large blooms necessitates that the number of growths on each plant be limited to three. The annexed engraving, fig. 89, is intended to illustrate a plant having just made its first break. In the point of the shoot can be seen the flower bud. This and all other shoots which have dotted lines through them are intended to be removed; the three stems which show no dotted lines at the top of the plant just below the flower bud and above those branches which are marked to come out, are to extend their growth, and in time produce flowers. The shoots which are retained should as fast as they grow be carefully tied to the stakes, as represented by fig. 86, p. 460. From this time all side shoots which spring from the main stem must be carefully rubbed out as fast as they appear. The removal of all superfluous

Fig. 89.—First Break.

growths concentrates the whole energies of the plant to the three stems retained until the next break takes place.

### "TAKING" THE BUDS—CROWNS.

If there is one detail in the cultivation of *Chrysanthemums* for large blooms that is of more importance than any other it is "taking the buds." Some persons may think this means pinching off the flower buds, but that is not so; it is the removing the growth shoots which form around the flower bud. These shoots are caused by the formation of the flower bud in the points of the branches. These are taken off, thus throwing the whole strength, so to speak, into the development of the bud retained. Experience with the different varieties will only thoroughly teach beginners in their cultivation the proper time to "take" the buds. If the buds are not retained at the right time for each variety it is useless to expect flowers of first-class quality. It is not a particular day of the month that all buds must be "taken," but the state of each individual plant must be considered when the wished-for bud appears, therefore no hard-and-fast line can be laid down as to the time when every plant shows its proper bud. As a general rule what is known as the crown bud is the one selected for producing the best blooms, but in some instances this particular form of bud will not produce the best results, as a difference of nearly a month must elapse between the "taking" of the correct bud on plants of some sorts and of other varieties. A close observance of the

peculiarities of each variety is necessary before any beginner can succeed satisfactorily. As a general rule plants which are grown by the method of what is termed the "large bloom" style show three buds during the season of growth; what is known as the first break, as represented by fig. 89, is formed from the middle of May to the same time in June. Some varieties which show the first bud among the earliest will send forth a second bud during July, but this cannot be considered other than a freak, owing possibly to the early maturation of the first break. In all cases buds formed at this time must be considered useless and should be removed. Taking the plants in a general way, the second, or what is known to growers as the crown bud, which fig. 90 faithfully represents, is formed at the points of the growing shoots in almost the same way as the first break. When this bud shows at the correct time for each variety and is "taken," then, all other things considered, it will develop into a perfect flower. The third break, which is caused by removing the flower bud from the "crown" break and allowing the branches to extend, produces what is known as the terminal bud. It is so named because it is the apex of growth, no other growths starting after the bud is formed. This is the best bud to select for the

Fig. 90.—Crown Bud.

production of good flowers of some varieties, particularly in the south of England.

As before stated, the time at which the crown bud forms is the all-important point to study. If it forms too early the flowers are coarse in the petals, which much oftener reflex than incurve in the case of incurved varieties. The flowers then are loose and flabby, more like inverted saucers than globe-shaped, which many varieties ought to be. They cover space enough, but are devoid of depth and solidity, the two most essential points in a good flower; and the dark varieties are not nearly so high-coloured as they ought to be. Let me impress upon beginners, then, the mistake which is often made in taking the buds too early. Disappointment is sure to follow, when quality is considered, if the buds are "taken" at too late a stage. This is again a fault, which results in flowers of a neat character, but much too small for high-class company. Some varieties under this treatment do not exhibit their true character when they are small. The locality in which the grower is placed has to be considered, as there is quite a fortnight, and in some cases a month, difference between the seasons of the buds showing in the south and north of England. Crown buds ought to be "taken" earlier in the northern counties than they can be with safety in the south.

Having given my reasons why the flower buds should not be taken too early nor yet too late, I will now endeavour to make

it as clear as I can which is the proper time to select them. The bulk of the Japanese varieties require a longer period to develop from the bud stage to the flower than do the incurved, therefore due thought must be given to this point. For instance, buds "taken" on the 6th of August will not be fully in bloom sooner than some of which buds were selected, say, the 10th of September. Watchfulness and comparison one year with another can only perfect the ambitious cultivator in this point. As a general rule around and south of London crown buds which are set from the 18th of August to the 1st of September are the most likely to produce desirable flowers. Those persons situated farther north will have the buds showing a little later, some perhaps at the same time; while in the extreme north many will not set their buds till quite a month later. There are some varieties—Japanese principally—which require their buds earlier than the date named.

I append a list of the sorts requiring early bud selection:—

*Buds "set" about August 10th.*—Boule d'Or, Meg Merrilees, Grandiflora, Golden Dragon.

*Buds taken about 1st September.*—King of Crimsoms, Golden Christine, Pink Christine, Peach Christine, Phidias, Queen of England, Golden Empress, Alfred Salter, Sir Stafford Carey, Empress of India, Hero of Stoke Newington, Princess Teck, Madame C. Audiguier, Thunberg.

Again, the flowers of some would be useless if the buds were set earlier than 1st September. These I purpose to class together. Where any particular variety is not named it is intended that the buds of these should be taken during what I propose to call the general time—viz., from the 18th of August to September 1st, and north of London all sorts should be "taken" not later than the time stated if possible. Fig. 90 represents a crown bud just formed. The growth shoots clustering around it should be cut off as denoted by the dotted lines across the shoots, and any other branches forming below those indicated must also be removed when it can be determined that the bud is perfect in form. The best time for this operation is in the early morning, or in the evening when the dew is upon the plants; the shoots at that time are quite brittle. If the stem is held secure in the left hand, and the young growths which are intended for removal be bent suddenly down one at a time, they snap off. After a little practice this method of taking off superfluous shoots is more expeditious than cutting them off with a knife; but if the operation is effected during the middle of the day, when hot and dry, the shoots are quite tough, and the risk of damaging the flower bud is much increased. When the growths are removed the whole energy of the plant is concentrated in the flower bud. As a safeguard against accident in the manipulation of the buds and shoots some growers retain one shoot at the point for a time, until it is seen that the bud is safely swelling to a good size; but this, I think, is wrong, as the growth is divided between the bud and the shoot retained, and the latter must to some extent rob the flower bud of its due amount of sap, but if care is used to perform the removal of the growths no danger need be apprehended. If a doubt exist in the mind that the bud has received injury from insects or otherwise, a day or two is sufficient to determine this. If so, it is useless to retain such a bud as those deformed, as such buds cannot develop into perfect blossoms. Retention of a growth shoot near the bud in this case is advisable; by so doing the number of flowers on each plant is not reduced by the loss sustained by the crown bud.

In the south of England, if the summer be exceptionally hot and dry, the buds must not be "taken" quite so early as the times stated, as some are likely to be deformed in consequence of their early development. In such cases it is much better to take out the bud and continue the leading shoot, which in due time will produce another flower bud. Let it be understood it is only in extreme cases of a very hot summer that this slight deviation of bud-selection should be made, and that not amongst growers north of London.—E. MOLYNEUX.

### SHADE FOR VINES.

Do we not often err in adhering too rigidly to the old notion that Grape Vines and fruit trees under glass should have all the sunshine possible, nothing in the shape of shading being afforded them? I think we do, and have long thought so. When the houses were constructed on a very different principle to those now built—that is to say, with a maximum amount of wood in the shape of rafters and sashes to fit on these, with double the number of sashbars now thought necessary—there was no need to shade the Vines, quite the reverse indeed. Now, however, the case is very different, as glass is in the ascendant, too much so I think, and our houses now get extremely hot in the summer and very much colder in the winter, this arising from the glass being a greater conductor of heat than wood. As a consequence on very hot days we have to ventilate very freely, or

otherwise scorching may and often does occur in spite of the ventilation. The admittance of much air, parched it may be, especially on days such as now being experienced (June 8th) with the wind in the east and a bright sunshine, naturally injuriously increases evaporation of moisture from the foliage, and this is diverted from channels where it is more required. Besides, it is this absence of moisture from the atmosphere and weakening of the growth that encourages the spread of red spider, and when once this gains a good hold it is all up with the prospect of a well-finished crop. Further, Vines badly infested with red spider are so much weakened thereby, that the following season they rarely bear so heavily as they ought otherwise to do.

We find that if we syringe a little thin lime water over the roof of any of the fruit houses that are in hot positions or have a great amount of glass surface, that this materially lowers the temperature directly under, and where it usually gets excessively hot, very much hotter in fact than those walking through a house are aware, and as a consequence little or no air need be given in front, an advantage obvious to all who take more than ordinary interest in such matters. Then, supposing the houses are frequently damped down, a very congenial atmosphere may be created, and if the thermometer under such conditions is run up to 90° during the day, and 5° higher when the house is finally closed, no harm will be done. On the contrary, a healthy and to me at one time surprisingly strong growth is produced. It must be understood that I do not recommend a heavy shading, and a thin limewash syringed over is neither heavy nor permanent, but if applied with a brush it would be too heavy, and a heavy shade at all times is bound to induce a flimsy growth. Should we experience a spell of dull showery weather our thin shading disappears, to be renewed in a few minutes when again needed.

It may be thought that this temporary shading even may interfere with the colouring, more especially of the white Grapes, but not if the latter are given the amount of time they really require to attain perfection. Black varieties may be fully coloured, and yet be sour, but not so the white sorts, and these must have time to mature. A direct sunshine will quickly colour them to a certain extent, but it very frequently disfigures them, as well as impairs the quality. Plenty of light they must have, but a thin shading on the roof and the Vine leaves overhead will not interfere with a perfect finish, always supposing neither shade is not overdone. A moderate canopy of healthy well developed foliage—this being assisted by the temporary shading—is really essential to the perfecting of either black or white Grapes, and I find that the bunches of any sort if unduly exposed are liable to be disfigured by the scalding of the berries, especially during the stoning period. Some of the best finished Muscat of Alexandria I have yet seen were shown at Bath last autumn by Mr. W. Taylor, and I observed that they were grown under abundance of healthy foliage. They were allowed plenty of time to ripen, consequently the colouring was natural and not artificial. Mr. Taylor, as many readers of this Journal are aware, is an expert in the art of ventilating, and therefore has less need to shade his roofs, but even he when at Longleat found it necessary to “do a little to it.” If this is the case with him, how much more so is it advisable in the case of those who are less experienced, or who cannot if they would attend so closely to the ventilation.

Not only is it necessary to shade however slightly modern houses, but it is imperative where cheap glass has been worked in. The latter very often has spots in it as powerful as a good lens, and unless shaded over nothing prevents burning in hot weather. We are bound to shade portions of our Peach range, and last season especially I wished I had freely shaded other portions thought to be safe, as I should then have saved a number of good Peaches from disfigurement. Even Peaches colour well without direct sunshine, the best we had being ripened in a light but not sunny position. A little shade is also beneficial to Melons, Tomatoes, Strawberries, and Figs, while Cucumbers like it on bright days.—W. IGGULDEN.

### NEW PLANTS AT REGENT'S PARK.

As mentioned in our report last week, numerous plants were certificated at the last Regent's Park Exhibition which could not then be noted, brief descriptions are therefore now appended.

*Nephrolepis rufescens tripinnatifida* (J. Veitch & Sons).—A handsome variety, with broad lance-shaped fronds, the pinnæ much cut on the lower side, and the divisions overlapping the others. Very bright green and plume-like in appearance.

*Rhododendron Gloria Mundi* (Veitch).—One of the greenhouse hybrids, with large well-formed bright orange-coloured flowers.

*Aparagus vericillatus* (Veitch).—A strong-growing dark green plant with numerous filiform leaflets round the stems.

*Gloxinia Ivanhoe* (Veitch).—A fine variety. Purple with a white margin and a dotted throat.

*Gymnogramma schizophylla gloriosa* (Veitch).—A grand robust form of this graceful Fern, the fronds freely divided and very proliferous.

*Imantophyllum Distinction* (Veitch).—Very showy, flowers bright orange with a pale centre; of good form.

*Todea grandipinnata* (Veitch).—Something like *T. pellucida*, but with large graceful fronds.

*Pteris tremula foliosa* (Veitch).—A strong-habited variety with tall fronds, the pinnules undulated on the margin; very effective.

*Cattleya Wagneri* (Hugh Low).—A handsome Cattleya. White with a pale golden tinge in the throat of the lip.

*Cattleya Reineckiana* (H. Low & Co.).—Sepals and petals white, lip large and streaked with crimson.

*Oncidium superbiens* (Sander & Co.).—Sepals and lips bright reddish brown, petals pale yellow barred with brown. It is similar to *O. macranthum* in habit, and bears similarly long racemes of flowers.

*Lissochilus lutescens* (B. S. Williams).—A curious little Orchid with small drooping racemes, the sepals and petals white, and the scoop-like lip tinged with yellow.

*Oncidium Kramerii majus* (B. S. Williams).—A very large and brightly coloured form of this strange Orchid.

*Dracena nobilissima* (E. G. Henderson & Son).—A broad-leaved variety, 6 to 8 inches across, dark red.

*Tuberous Begonia Charmer* (Laing & Co.).—Single, bright rosy crimson with a white centre.

*Anthericum liliastrium majus* (T. S. Ware).—A variety with large pure white flowers.

*Pæony Festiva maxima* (T. S. Ware).—A large double variety of the herbaceous type. White with a few crimson streaks. It was also certificated at Kensington on the previous day.

A CIRCULAR just issued reminds the public that the ROYAL HORTICULTURAL SOCIETY'S PROVINCIAL SHOW will be held in the Botanic Gardens and Wavertree Park, Liverpool, from June 29th to July 5th, 1886, inclusive, the prices of admission being 5s. on June 29th, 2s. 6d. on June 30th, and 1s. on July 1st, 2nd, 3rd, and 5th. The Show will be open to Fellows of the Society at 12 noon on June 29th, and to the public at 1 P.M., closing at 7 P.M. On other days the hours of opening and closing will be 10 A.M. and 7 P.M. respectively, except on Saturday, July 3rd, when the hour of closing will be extended to 8 P.M. Numerous varieties of plants, fruits, flowers, vegetables, horticultural implements and appliances, will be exhibited, for which, under various classes, the sum of £1200 will be awarded in prizes. These prizes are open to all competitors who reside in the United Kingdom, but no exhibitor can obtain more than one prize in any class. Valuable awards, ranging from £1 to £20, are offered for Orchids and other species of plants; also for cut flowers, fruit and vegetables. Table decoration, bouquets, and grouped garden produce will greatly augment the attractiveness of the Show, as well as offer substantial benefits to successful competitors. Eminent firms of seedsmen have offered prizes for various kinds of vegetables which are, severally, among their specialities, and a most novel and interesting exhibition will be that of horticulture on board ship, for which medals will be awarded according to merit. On Saturday, July 3rd, and Monday, July 5th, there will be a Cottagers' and Artisans' Show. The exhibits of horticultural and botanical literature, science, and art, will be divided into three sections:—Section A., Home and foreign literature of gardening, embracing instruction (elementary and advanced), models, diagrams, apparatus, &c. Section B., Technical art, such as surveying, plan and architectural drawing. Section C., Botanical and decorative art, such as photographs, and drawings in water colours and oil, of flowers, fruits, trees, and garden landscapes. An incentive to amateurs is offered in a competition for a hand-painted china or terra cotta vase, tile, or plate, the subject being flowers, fruit, or foliage. The awards will be silver-gilt, silver, and bronze medals.

— APPLICATIONS for space for implements, garden structures, tools &c. have been numerous, including space for boilers entered for the boiler contest. All modes of heating, ornamenting, and ventilating conservatories, &c., meteorological instruments, wirework, tenting, &c., will be prominently shown. Certificates will be awarded for any special novelty approved of by the Judges that may be brought under their notice; also one or more gold medals for the most meritorious aggregate displays in any or all of the classes. There will be a conference on the nomenclature of Orchids on Wednesday, June 30th, in which some of the most eminent men of the day will participate. The whole Exhibition will be one of great interest and value, not only to the general public, but also to scientists and practical gardeners; and persons intending to visit the International Exhibition of Navigation, Travelling, Commerce, and Manufacture, should make a point of doing so while the Royal

Horticultural Society's Show is in operation. The main entrance to the Show will be at the junction of Wavertree and Exhibition Roads, while another has been provided for at a point in the Exhibition Road opposite to the main entrance of the "Shipperies," so as to enable visitors to pass freely from one Exhibition to the other. Every requisite will be provided in the way of refreshments for the comfort and enjoyment of visitors, and two military bands will perform each day, that of the Scots Guards having been engaged for the opening and succeeding days—viz., June 29th and 30th. With the exception of the space occupied by one large tent, which will be filled with Roses, and one or two smaller ones, the whole of the hotanic gardens, including the lawns, will be available to visitors as a promenade.

— INTENDING exhibitors of plants, &c., are reminded that the entries close on Monday next, the 21st. It is expected that this will prove one of the largest and most important of the exhibitions ever held by the Society. Great progress is being made in laying out the grounds, and many of the hothouses are already erected. The implement exhibition being of great extent only fine weather is required to make it a thorough success. Vans will be in readiness at Edge Hill and other railway stations to convey the plants, &c., to the Exhibition, on giving notice to Mr. Richardson, Curator, Botanic Gardens, Liverpool, when they may be required; and the several leading railway companies have agreed to carry the plants on their return journey at reduced rates. Prompt decision on the part of exhibitors now will greatly facilitate the work of the Managers.

— THE ROYAL BOTANIC SOCIETY'S EVENING FETE will be held on Wednesday, June 30th, 1886, in the Garden, Regent's Park. There will also, as usual, be an exhibition of floral decorations, in which the following will be classes:—1, Floral decorations arranged for a dinner-table 10 by 5; 2, Ditto, ditto, dressed ready for use; 3, Ditto, three groups for ditto, only one kind of flower in each group; 4, Ditto, leaves of hardy plants and Grasses only; 5, Foliage and flowers, suitable for a sideboard; 6, Group of plants, arranged for the decoration of a recess, alcove, or fireplace in a room; 7, Standing basket, furnished with plants suitable for growing in a living-room; 8, Hanging basket, with growing plants; 9, Bridal bouquet; 10, Ballroom bouquet; 11, Group of flowers, &c., stalks in water, and neither tied nor wired; 12, Flowers (either cut or on the plant) which only expand at night. Medals are also offered for the following:—A, Arrangements of flowers, leaves, &c., for personal adornment, such as wreaths, chaplets, and the like, and also for use in dress trimming and ornament. These may be prepared ready for attachment to the dress, or the dress may be exhibited as ornamented. B, Lamps or illuminants for ornamental outdoor or conservatory use. C, Self-contained garden and conservatory fountains. D, Works of art. The Glass Corridor and Museum will be reserved for the exhibition of paintings and carvings of trees, plants, flowers as pictures, or on glass, china, wood, or other material. The prizes vary from £5 to 10s.

— THE TUBEROUS BEGONIAS AT MESSRS. J. LAING & Co.'s NURSERY, FOREST HILL, will shortly be in grand condition. Already there is one large span-roofed house filled with strong plants in flower, representing the superb varieties that have been raised by this firm in recent years; but there are numbers of others advancing to prolong the display, including many very promising novelties which we shall have occasion to notice shortly. Outside considerable space is this year devoted to seedling Begonias, of which there is a stock of 116,000. These have just been planted in beds as in previous seasons, and will in a few weeks' time produce a magnificent display. In other houses are choice collections of useful Orchids, which now constitute one of the features in this nursery, and Caladiums also occupy much space, most of the best varieties being grown.

— THE WATER COLOUR DRAWINGS OF ORCHIDS exhibited by Mr. A. Foord Hughes at the last meeting of the Royal Horticultural Society were tasteful and accurate representations of some choice varieties from Mr. A. H. Smee's collection at Wallington, and were much admired by many visitors. More attention is now being given by artists to these popular plants, which from their varied floral forms and colours would make some charming pictures. Numerous examples of such works can be seen in Miss M. North's gallery at Kew, which combine botanical accuracy with artistic effect.

— A MANUAL of twenty pages, by Mr. Alfred Stead, entitled "HOW TO GROW PEACHES, NECTARINES, AND APRICOTS IN SMALL

GARDENS," has been sent to us. The author has endeavoured to make the subject clear to the ignorant, but we doubt if his endeavour to do so by counting the number of buds to be removed and shoots to retain will be so well understood as he anticipates. We think he is in error in saying the Apricot scale produces a caterpillar; at least, we have not seen any of this kind. The manual is published by Messrs. Hamilton Adams & Co., London. We have another treatise on Peaches, Nectarines, and Pears of a little more substantial character by Mr. Robert Smith, which we will refer to again.

— MR. T. WINKWORTH, The Gardens, Childwall Hall, Liverpool sends us a flower truss and leaves of HELIOTROPE WHITE LADY, which are much the finest we have ever seen. The leaves are 7 inches long and 3½ inches broad, stout, vigorous, and dark green; the flower truss is over 1 foot in diameter, and our correspondent states this is the average size. The flowers are not pure white, being very faintly tinged with colour, but they are extremely fragrant, and the variety evidently succeeds under Mr. Winkworth's management.

— WE have received a copy of the twenty-second thousandth impression of Mr. E. W. Badger's "COTTAGE GARDENING," which has been revised and much enlarged. The mere fact of this useful little work having attained such a circulation is sufficient to commend it to those requiring a sound guide to cottage gardening.

— MR. J. HAM sends us the following note on ASPARAGUS WITHOUT BEDS:—"Enclosed is a sample of Asparagus grown without preparation of the ground in any way. It is apparently from a seed carried by the birds and dropped upon a place in my garden, where there is not a foot depth of soil, resting on a very stiff clay subsoil, without drainage, except a gradual natural decline. I have never seen any so fine as it usually is, although others may have still larger. This weighs 3½ ozs. The root is about five years old." [It is a very fine head indeed; a length of 7 or 8 inches tender.]

— EARLY STRAWBERRIES.—Some plants of King of the Earlies and The Captain Strawberries, which were sent us by Mr. Laxton, have fruited this season, and we find them the earliest of any other varieties with which we are acquainted, earlier even than Pauline, which was grown alongside, by quite a week. We have received fruit of Princess of Prussia from Mr. J. Gibson of Draycot Gardens, which were grown in the open air and which are perfectly ripe. May not this be Princess Frederick William of the "Fruit Manual," an early and highly perfumed Strawberry, good alike for forcing and open air culture?

— HORTICULTURAL CLUB.—The last dinner and conversazione of the season was held on Tuesday, June 8th, under the presidency of Mr. John Lee, Chairman of the Club. A valuable and interesting paper (see page 479) was read by Mr. C. T. Druery, on variation, with especial reference to Ferns. In the after discussion, in which Messrs. Lee, Pearson, Cousens, and others took part, many valuable facts were elicited. The Club has thus brought to a successful issue a series of interesting meetings, in which some of our leading botanists and horticulturists have taken part. It was announced that the annual excursion would take place on July 28th, and would include a visit to Heckfield and Strathfieldsaye.

— AN American horticulturist, writing in *Meehan's Gardeners' Monthly*, has the following note on the culture of STREPTOSOLEN JAMESONII:—"I set out some young plants from cuttings in May, in the open air, which soon grew to be bushy plants. I pinched them in, with the idea of making them stronger, which operation we perform on Bouvardias, Chrysanthemums, Heliotropes, Stevias, Eupatoriums, and many other plants; but I made a mistake. Some of my Streptosolens I did not pinch, but left only three or four shoots, which grew quite strong, from half to 3 feet high. They were potted in September, in rich loamy soil, and, on account of their many fibrous roots, soon started to grow again, and in about two weeks were brought to a sunny exposure in the house. With proper repotting and a moist temperature, from 50° to 60°, they develop their beautiful numerous clusters of orange yellow tubular flowers, clusters almost as large as Hydrangea, commencing to flower the latter part of January, and continuing to May. They afford a good show of charming blooms, far more perfect than those that have been pinched in. The shoots intended to bloom need the whole season's undisturbed growth. Nature not having provided them with stalks quite strong enough to hold up their exquisite heads, the principal points in their cultivation are to leave a limited number of shoots, and to skilfully aid them by proper supports."

— THE June number of the "Botanical Magazine" gives figures of the following plants—T. 6878, *ANTHURIUM SPLENDIDUM*, is a magnificent Aroid, which was introduced from New Grenada by Mr. W. Bull in 1882. It has been exhibited on several occasions, and is notable for the beautiful metallic green colour of the puckered or bullate leaves. T. 6879 portrays *Grevillea Hookeriana*, a native of the Swan River Territory of South-Western Australia, "growing in dry places along the coast, as near King George's Sound as the Gardener River, and at Doubtful Island bays. It was discovered by Preiss, and collected afterwards by Drummond and others. The specimen figured was raised from seed sent by W. R. Guilfoyle, F.L.S., Director of the Melbourne Botanical Gardens, which flowered in the Royal Gardens in January of the present year." The leaves are pinnate with linear divisions, the perianth yellowish, and bright red styles.

— IN the same work T. 6880 shows *SOPHRONITIS VIOLACEA*, a Brazilian species, which was discovered by Gardner in 1837, "who in a note says that he found it only once, and then as a single small tuft on the trunk of a large tree." It was first described by Lindley, from a specimen flowered in 1847 by Mrs. Cannon of Stratford Green. In 1852 Reichenbach published a much fuller description in the *Linnaea*, from specimens sent by Regnell. He states that it is common on the Organ Mountains. It is a pretty dwarf species, with oval pseudo-bulbs about 1 inch long, and bright rose-coloured flowers  $1\frac{1}{2}$  inch across. Though not so showy as the well-known *S. grandiflora*, it is a charming Orchid, and forms a good companion for that. T. 6881 is *Roydsia suaveolens*, an East Indian plant found on the borders of tropical forests at the base of the Eastern Himalayas, "scenting the air when in flower with a delicious fragrance." The leaves are elliptical, bright green, are persistent, the racemes of flowers being produced from the axils, the numerous stamens form the most conspicuous portion of these being white or yellowish; the calyx being dull coloured, and the corolla absent. T. 6882 is *Tillandsia inflata*, a Brazilian Bromeliad, related to *T. psittacina*, but with overlapping bright rosy bracts and yellow flowers. It was introduced to cultivation by M. Binot in 1880 and first flowered by M. Truffaut at Versailles.

### VINERY WORK IN JUNE.

JUNE, in my opinion and experience, is one of the busiest months in the whole year in vineries. All midseason and late Vines make more wood now than any other time. Bunches and berries on all late varieties require thinning; and stopping, tying, and syringing must have daily attention. Watering at the roots, too, is of the greatest importance now, and those who wish to have their Grapes in the best possible condition when ripe must deal liberally with them. Old borders where the soil is stiff and the drainage not very open will not be very porous, and they will not require so much water as newer borders where the soil is still in lumps and the drainage quite free. A border of this kind can hardly have too much water in dry sunny weather, and once every ten days is not too often to give it a complete soaking. When showers moisten the surface of the ground it is apt to become rather deceptive, as a wet surface does not always indicate a humid soil underneath, and it is this which checks the Vines and ruins the Grapes. We have frequently given our outside Vine borders a thorough watering the day after we had rain, as a well-drained Vine border requires more water than an ordinary piece of the garden where the drainage is only natural and the roots few. Too dry borders are highly injurious, as the wood fails to develop as it should do; the leaves are small, the berries do not gain their proper size, and both the fruit and wood ripen prematurely, and all this not only injures the Vines at the time, but its injurious effects are experienced in years to come. Apart from this, too, sparingly watered Vines soon become infested with insects, and these are enough at any time to spoil the Grapes. The most water is required when the berries have been thinned and until colouring has fairly commenced. It is during that period every part is developing and the demands from the soil are at their greatest. Late Grapes, which now require thinning, should be thinned much more than early ones. The berries of Gros Colman and some other late sorts gain a very large size, and bunches which appear as mere skeletons after thinning swell, under good treatment, until they are complete in all parts.

Black Alicante is an enormous setter. As a rule six berries have to be removed for every one left. Lady Downe's is not so free, and very often there are a great many small berries amongst the large ones in the bunches of this variety. These small ones would never swell and must all be clipped out; but the main reason why late Grapes should be freely thinned is that when the fruit is ripe the berries may not be quite in a solid mass, but sufficiently apart to admit of the air passing through them when they are hanging in a damp atmosphere during the short sunless days of late autumn and winter.

A general cutting away of shoots should never be practised. We have known the wood in some vineries allowed to grow until the whole roof was a mass of shoots, then on a certain day a general cutting back took place, and "daylight" was let in by shortening every shoot to three or four joints beyond the bunch. I have noticed soon after this the Grapes did not swell for a time, and the shoots appeared as if they were unable to start into growth again. Now, whatever you do, avoid this—it is suicidal. If properly treated there should never be occasion to do it, as all the shoots should be stopped long before they cover the roof; and when, by any chance, this happens, thinning and shortening should be done by degrees. In this case we would clear away the top growths one day in a week or so afterwards the bottom ones would be taken, and in another week the middle would be cut back. By this plan the flow of sap would never be checked to any great extent, and the wood and fruit would go on swelling freely. Stopping the shoots, however, should be followed in a systematic way, and should begin as soon as the shoots are long enough to require stopping, and go on until growth ceases, then the results of it are never experienced in any injurious form. All the best Grape-growers have found that to stop the shoots two joints beyond the bunch is a good place to begin, then a fresh growth is produced; it is stopped at every joint until there may be five or six leaves beyond the bunch, when growth is restricted altogether, and while the light is not too much obscured by this length of shoot the fruit has every opportunity of perfecting.

We only make one exception to this rule, and that is when Grapes are ripening during hot weather in June or July we generally allow the young growths to extend a little to afford shelter and shade to the fruit, as almost all Grapes will colour better under a little shade than when exposed fully to a midsummer sun. The Black Hamburgh colours more intensely under shade than when exposed; the same may be said of Gros Colman. Syringing Vines is not such a common practice now as it was at one time; many think it injures the bloom on the fruit, and when dirty water is used or water containing lime it may spot them, but clean water is not injurious, and Vines which are frequently syringed until the fruit begins to colour are generally very free from insects. This is a recommendation for syringing which deserves notice. In warm weather I do not think it is a good plan to syringe the Vines at 3 P.M. or 4 P.M. while the sun is still shining brightly on them, but if they are syringed at 7 P.M. or 8 P.M. it is a cooling bath for them after a hot day, and the dewdrops which are seen hanging from the edges of the leaves in the morning after this are highly conducive to the health of the Vines. Does some youngster ask "Who is going to syringe Vines at 8 P.M.? That is overtime." Well, my man, if it was an impossibility for you to see to it once or twice a week in hot weather I would do it myself. Vineries now require to be ventilated freely. On warm mornings the top lights may be let down a few inches by 7 A.M., and top and bottom lights may be open by 10 A.M. A very close dry atmosphere must be avoided. The surface of the border or floor should be damped several times daily, and the house should be closed in the afternoon to secure a temperature of 85°.—M.

### ODONTOGLOSSUM VEXILLARIUM.

AMONGST the numerous handsome Orchids at the Royal Botanic Society's Show in Regent's Park last week, none attracted so much admiration as the magnificent specimen of *Odontoglossum vexillarium* shown by Mr. James Douglas, gardener to F. Whitbourne, Esq., Great Gearies, Ilford. By the unanimous consent of all the leading orchidists present it was distinguished as the finest specimen in the exhibition, and it is probably the grandest example of this beautiful species that has ever been shown in London. One great point in its favour is that it is a *bona-fide* plant, having been obtained with several others as a small piece ten years ago, and grown on to its present size; but it has never been so fine as the present season, and, as will be seen from the illustration (fig. 91), when sketched at the show named, it was "a mass of flowers" concealing the foliage. It had forty-seven spikes, or a total of 289 flowers, all of good size and form, the variety being a pretty and delicately coloured one. *Odontoglossum vexillarium* is a puzzle to some cultivators, but at Great Gearies the plants succeed admirably, making vigorous growth each season, and always looking well; yet there are no secrets in the cultivation, no complicated system of treatment to describe, but simply the care of an experienced, observant gardener. Mr. Douglas adopts the same method which Mr. B. S. Williams recommends—namely, growing the plants during the winter in the Cattieya house until the flowers are appearing, and they are then removed to the cool house, where the flowers last longer, and in this house the plants remain throughout the summer, one point being most carefully observed at all times—namely, never allowing them to become dry at the roots. This is important; and so is another matter—i.e., keeping the plants free from insects of all kinds, and the closest attention to this will be well repaid.

When first described, in 1867, by Professor Reichenbach, *Odontoglossum vexillarium* was announced with much secrecy, and it was said that neither its native home nor the introducer's name was known, and the person to whom it had been lent was only to take "three looks at it."

Several years later, however, further particulars were obtained, and it appears that the plant was discovered by Bowman, on the "Western slope of the Andes of New Grenada." It was sent home by several collectors, but the plants when received were generally either dead or had suffered too much to recover under cultivation. There has always been much difficulty attending the importation of this *Odontoglossum*, and probably none has proved so disappointing to nurserymen. Mr. Henry Chesterton, however, at last succeeded in sending to Messrs. Veitch and Sons, Chelsea, living plants that endured the ordeal of transmission, and of these some flowered in 1873, from which figures were prepared for the "Botanical Magazine" (t. 6037) and other periodicals. Since then consignments have been occasionally received in good condition, but it re-

when cut and placed in water—indeed, they are quite unsuited for that purpose.—L. C.

#### SAXIFRAGAS.

THE Saxifragas should have a place in all collections of hardy plants. *Saxifraga Wallacei* is an extremely pretty species at this time of the year, and being dwarf it is very useful for borders and rockeries. It may be also used for spring bedding, for generally in an early locality it comes into flower before the beds are required for summer plants. It is pretty with its masses of green foliage and white flowers. It is of easy cultivation, and should be propagated from cuttings. The best time to take

Fig. 91.—*ODONTOGLOSSUM VEXILLARIUM*.

quires careful packing, and good treatment after it reaches the cultivator's hands, or failure results.

This *Odontoglossum* has been termed the Queen of the Orchids, and it merits the title, for when well grown it is a lovely plant, and has an admirable appearance amongst Ferns. The varieties are very numerous, and many of them have received names indicating their colour. Some have bright rosy-tinted flowers, and others are nearly white, the latter being usually the largest. Then in some the one portion of the flower is pale while the other is of a rosy hue termed bicolor; and in still others a yellow blotch is strongly marked in the centre, and these are termed tricolor. Two of the best coloured varieties are Sir Trevor Lawrence's superbum and Mr. B. S. Williams's splendens, both of which are remarkable for the rich rosy crimson hue of the flowers. A distinct form sent out by Mr. W. Bull, under the name of *O. vexillarium rubellum*, is a free-flowering variety, and flowers much later than the others, usually in early autumn, long after the ordinary vexillariums are over. It is a most useful Orchid in all its forms, but its flowers last a very short time

the cuttings is about the end of this month. They should be taken carefully, then inserted into some good soil consisting of equal parts of loam and leaf mould, with a good dash of sand in it. The best way is to place the prepared soil on a border to the thickness of about 3 inches; then insert the cuttings, taking care to firm them well and give a good watering. Place a cloche or bellglass over them, giving some shading on very bright days. They require no air until rooted, which is generally in about a fortnight or three weeks; when rooted, air should be given gradually until properly hardened off, when the bellglass may be taken away. The plants will be then quite large enough for planting out in clumps on the borders or rockeries; or if required for spring bedding they may be left in the cutting beds until October, when they should be planted in their required places.

*Saxifraga Burseriana* is also well worth mentioning, for it is a beautiful species with silvery foliage and lovely white flowers; but it is generally a month later than *S. Wallacei*, but grows to about the same height—viz., from 4 to 6 inches.—AN OUTSIDE FOREMAN.

## ROYAL BOTANICAL AND HORTICULTURAL SOCIETY OF MANCHESTER.

THIS Society's great Show is open for a week, commencing on the 11th and continuing until Friday the 18th inst. This Society is so well known to be the most prosperous in this country, and at none are such collections of Orchids ever brought together. On the present occasion they are finer than usual, and competent authorities state it is the finest display of these plants ever seen at Manchester. The same view is expressed about the herbaceous and alpine plants. The fruit has also wonderfully improved, both in the quality and number of the exhibits. Great credit is due to Mr. Bruce Findlay, the Council of these Gardens, and all who assist to render these exhibitions successful. The entire management being in the hands of Mr. Findlay, some of the success of this Exhibition is undoubtedly due to the kindly welcome extended to all who visit these Shows.

**ORCHIDS.**—It is indeed questionable if ever before were such a display of Orchids to be seen in bloom at the great Exhibition of this Society. The plants exhibited numbered about 500, and half of these were in competition in the eight classes provided for them. The display of Orchids were indeed lovely, and they extended all round the large exhibition house, which we do not think has ever before been the case on any previous occasion. G. Hardy, Esq., Timperley, may be regarded as the premier competitor, for he succeeded in carrying off four of the leading prizes in six classes. In the class for fifteen exotic Orchids Mr. G. J. Hill, gardener to G. Hardy, Esq., Pickering Lodge, was well ahead with some magnificent plants of *Dendrobium Wardianum* with fifteen spikes, several of the pseudo-bulbs being 4 feet in length and furnished with flowers nearly the whole of that length. *Dendrobium Paxtoni* was another grand specimen, fully 5 feet in height and 4 feet through, and covered with its drooping panicles of yellow flowers. *Lælia purpurata* was grand with over forty of its delicate and gorgeous flowers. *Cattleya Mossiæ* was also very fine, being from 3 to 4 feet through and covered with large fine flowers. *Cattleya Skinnerii* was lovely with about twenty-five spikes of bloom, many of them carrying four and five flowers each. The number of flowers and spikes on *Odontoglossum vexillarium* it was impossible to count, for the plant, which was about 3½ feet in diameter, was covered with its large flowers. A dark form of this beautiful *Odontoglossum* was equally well flowered, and was about 2 feet 6 inches across. A fine healthy plant of *Vanda suavis* had seven large spikes. The fine old *Aerides odoratum majus* had no less than thirty spikes, while *Cattleya Mendeli*, a fine form, had no less than thirty-four flowers. *Cypripedium Lawrencianum* was a noble specimen with nearly forty flowers, while *C. caudatum roseum* had seven of its curious flowers. *C. Stonei* had five branching spikes, and *C. superbiens* was covered with blooms, being between 2 and 3 feet across. *Dendrobium suavisima* was about 2 feet across, and well bloomed. Some idea of the effect of this collection may be gained from the enormous quantity of flowers and the size of each of the various plants. Mr. J. Cragg, gardener to A. Heine, Esq., Fallowfield, was placed second in this class, and although the plants were good they were poor in comparison with those which gained the premier position. The most striking plants, however, were *Cattleya Mossiæ*, 3 feet in diameter and covered with bloom, and *Dendrobium thysiflorum*. Mr. A. Cole, gardener to Joseph Broome, Esq., Didsbury, gained the remaining award, and staged capital examples of *Odontoglossum crispum* and *Aerides Fieldingi*.

For nine plants, Mr. J. Cragg took the lead with large healthy well-flowered plants. This collection was remarkably good. *Cattleya Mossiæ*, a large panful (made up), 4 feet in diameter, had about 125 flowers; *Cattleya Mendeli*, thirty-six, very good; *Calanthe veratrifolia*, twenty-two spikes, several of them being 4 feet high. *Dendrobium Devonianum* was especially good, being fully 3 feet high and as much through, covered with blooms. *Dendrobium Paxtoni* was also good, being 5 feet high and from 3 to 4 feet through, and well flowered. *Odontoglossum crispum* was 3 feet 6 inches through, and one mass of bloom. *O. Roezii* was very fine, being nearly 3 feet over and well flowered. *Cypripedium Lawrencianum* was remarkably well grown, having forty-five flowers. Another form of *Cattleya Mossiæ* with forty flowers completed this beautiful collection. Mr. G. J. Hill was a good second with *Lælia purpurata*, seventeen flowers; *Dendrobium Jamesianum*, well-bloomed, and about 3 feet through; *Cypripedium Parishii* was very handsome, with eleven spikes. A light form of *O. vexillarium* was well bloomed, being 3 feet across; *Cattleya Mossiæ* was about the same size, with plenty of flowers; *Masdevallia Harryana* was also very good. Mr. Elphinstone, gardener to John Heywood, Esq., Stretford, was accorded the remaining prize.

For six plants, Mr. G. J. Hill took the lead, having a grand *Lælia purpurata*, fifteen flowers; *Odontoglossum citrosimum roseum*, with nine large spikes; *O. vexillarium*, twenty-five spikes; *Cattleya Mossiæ*, 2 feet in diameter and well bloomed. *Dendrobium clavatum* was also fine, the flowers being bright yellow. *Dendrobium Wardianum*, a well-flowered plant, completed this collection. Mr. R. Elphinstone was a good and close second with *Lælia purpurata*, with the same number of flowers as in the previous collection; *Cattleya Mendeli*, with twenty-one flowers; *Cattleya citrina*, a large plant on a block, with thirty-one fine flowers; *Odontoglossum caudatum*, with twenty-one spikes; and a well-flowered *Cattleya Mossiæ*, 3 to 4 feet through. Mr. R. Johnston, gardener to T. Shalter, Esq., third, having particularly noteworthy *Mormodes luxatum eburneum*, and a very fine dark-coloured form of *Cattleya Mendeli*.

For ten *bona fide* specimens—made up plants disqualified in this class—Mr. G. J. Hill was again to the fore with grand examples of *Aerides Veitchii*, with three large branching spikes, *Dendrobium crassinode* with twelve well-flowered pseudo-bulbs, *Cypripedium Stonei* three spikes, and a very good plant of *Odontoglossum vexillarium*. Mr. A. Cole was second, and staged most creditable plants, *Cattleya Lawrenciana* with five flowers on one spike, and *Sobralia macrantha* with seven of its beautiful flowers. Mr. J. Cragg was awarded the remaining prize and staged most creditable plants. For three *Vandas* Mr. A. Cole was the only exhibitor, and was deservedly awarded the first prize for *Vanda teres*, a magnificent plant with 100 fully expanded flowers and in good health. Another of the same species with half the number and *V. suavis*, very fine with seven spikes of bloom. For six *Cattleyas* Mr. G. J. Hill was well to the front with a light form of *Cattleya Mossiæ*, *C. Skinnerii*, *C. Mendeli*, and two other dark forms of

*C. Mossiæ*. These plants were about 3 feet in diameter and in grand health. Mr. J. Cragg was placed second, and had in his collection three very creditable plants, although smaller than those in the previous exhibit.

In the nurserymen's class for sixteen plants Mr. James Cypher, Cheltenham, was well first, and staged well-flowered plants of *Cattleya Mendeli grandiflora* 3 feet through, *C. Mossiæ* about the same size, a fine form of *C. Mendeli* with nine flowers, *C. Mossiæ Rothschildiana*, very good with a remarkably large lip; *Odontoglossum citrosimum roseum*, the finest dark lip variety in the Exhibition; *Anguloa Clowesii* with fourteen flowers, *Vanda suavis* with three spikes, *Lælia purpurata* *Brysonia* particularly good, *Epidendrum vitellinum majus*, between 2 and 3 feet through, one mass of blooms, and a good pan of *Cypripedium Lawrencianum*. Messrs. Heath and Sons, Cheltenham, were placed second, and Mr. H. James, Castle Nursery, West Norwood, third. The second collection contained *Aerides Lobbi*, very good, with eight large spikes; *Aerides virens*, with the same number; a large pan of *Dendrobium Parishii*, and a good specimen of *D. Dearei*, with seven or eight spikes of its pure white flowers. For ten plants Mr. H. James took the lead, followed by Mr. Cypher and Messrs. Heath & Sons in the order named. The first collection comprised *Cypripedium barbatum superbum*, *Masdevallia Harryana*, *Cattleya Mendeli*, a large plant of *Cypripedium Lawrencianum* with thirty flowers, a dark form of *Odontoglossum vexillarium*, *Cattleya Mossiæ*, and *C. Warneri*, all being in good health and well bloomed. Considering the enormous quantity of Orchids staged both for and not for competition, scarcely a plant amongst the whole could be considered unhealthy, the foliage throughout being green and the plants and flowers perfectly fresh.

**STOVE AND GREENHOUSE PLANTS.**—These, perhaps, were not so numerous or so excellent as we have been in the habit of seeing at this Society's exhibitions in the past. Many of the plants, however, were excellent examples of culture. In the amateurs' class for ten plants in flower Mr. F. Nicholson, gardener to the Earl of Zetland, Upleatham, was well to the front with neat well-grown examples of *Anthurium Schertzerianum*, fine; *Clerodendron Balfourianum*, *Stephanotis floribunda*, very good; *Statisia profusa*, about 4 feet through and profusely flowered; *Allamanda grandiflora*, very fine; *Dracophyllum gracile*, very healthy and fresh; *Aphelaxis macrantha* purple, good; and *Franciscea calycina* major. Mr. G. Paul, gardener to S. Schloss, Esq., Bowdon, was a close second, and staged grand examples of *Boronia elatior*, well bloomed; a grand *Stephanotis floribunda*, 5 to 6 feet through and full of bloom; a good *Bougainvillea glabra*, and *Azalea* Sir Charles Napier. Mr. Roberts, gardener to A. Nicholson, Esq., third, having a fine *Anthurium Schertzerianum*, *Stephanotis*, and an *Aphelaxis*. In the corresponding nurserymen's class for ten plants three collections were staged. Mr. J. Cypher was accorded the premier position with handsome well-grown plants of *Erica Cavendishiana*, 5 feet through and entirely covered with bloom; *Erica depressa*, about the same size, was equally good; *E. tricolor elegans* and *E. affinis* were also superb; *Ixora Williamsii*, about 5 feet high and as much through, was covered with its very large trusses of bloom; *Dracophyllum gracile*, very fine; *Clerodendron Balfourianum*, *Anthurium Schertzerianum*, good; *Azalea Souvenir de Prince Albert*, well flowered, a large plant; *Aphelaxis macrantha*, superb; and the same may be said of *Hedera tulipifera*. Mr. J. F. Mould, Pewsey, was placed second, and staged well-grown plants of *Statisia profusa*, *Ixora coccinea*, *Dipladenia profusa*, very fine; and a large well-flowered plant of the old *gloriosa superba*. Mr. H. James received the remaining prize.

**FINE-FOLIAGE PLANTS.**—Considering the foliage plants on the whole they were equal to those of past years, while the collection staged by Mr. W. Nicholson in the amateurs' class for ten plants have rarely if ever been excelled at any exhibition. This collection was well first, and comprised *Croton Warreui*, 7 feet in diameter and perfect in colour; *C. Johannis*, very fine, 6 feet in diameter, colour good; *C. majesticus*, about the same size and in the same excellent condition; *Davallia fijiensis plumosa* 7 feet across, very fine, a perfect example of cultivation; and the same may be said of *Kentia Fosteriana*, *Chamaerops humilis*, *Dion edule*, and *Kentia Belmoriana* were also handsome effective plants. A large *Cycas revoluta* and *Gleichenia Mendeli* 5 feet through, fresh and healthy, completed the collection. Mr. C. Roberts was placed second, and also staged large, noble healthy plants of *Cycas circinalis*, *Encopalartos villosus*, *Thrinax elegans*, *Latania borbonica*, and *Croton Johannis*. Third Mr. G. Paul, his best plants being *Anthurium Veitchii*, very good, *Cocos Weddelliana*, *Gleichenia rupestris*, and *G. Mendeli*. Mr. G. Williams, gardener to S. Baerleiu, Esq., Didsbury, was awarded an extra prize in this class. In the nurserymen's class for eight plants Mr. Cypher was well to the fore with large well-grown examples of *Croton Victoria*, *Cycas revoluta*, *Kentia cantherburyana*, *Latania borbonica*, *Kentia Fosteriana*, and *Thrinax elegans*; Messrs. H. James and J. F. Mould being the remaining prize-winners in the order named.

**DRACENAS.**—These plants, as usual, were very fine, and Messrs. R. P. Ker & Sons, Aigburth, Liverpool, secured the first position for twelve plants with excellent examples of *D. superba*, *Goldiana*, *Weismanni*, *Gladstoniae*, *recurva*, *Robinsoniana*, *picta*, and *vivicans*. Mr. H. James was a good second, and also staged noteworthy plants. Mr. J. F. Mould secured the remaining prize, four collections being staged. In the amateurs' class for six plants Mr. A. Cole took the lead with very finely developed plants of *Robinsoniana*, *Baptisti*, *Lindenii*, *Youngii*, *Shepherdii*, and a particularly large plant of *D. Anerleyensis*. Mr. G. Williams was placed second with rather smaller plants; and Mr. G. Kemp, gardener to Mrs. Sykes, Stockport, third with well-furnished healthy plants.

**CROTONS.**—These plants were not up to their usual standard of excellence. The fine examples generally contributed by Messrs. R. P. Ker & Sons were missed. In the nurserymen's class only one exhibitor staged, and the plants, although large and well furnished, were rather deficient in colour. Mr. J. F. Mould, was, however, awarded the first prize. In the corresponding amateurs' class for six plants Mr. A. Cole was placed first with moderate-sized plants of *C. Queen Victoria*, *C. Disraeli*, *C. Prince of Wales*, and *C. Evansianus*, this being the only exhibit.

**PALEMS AND YUCCAS.**—Only two collections were staged for the prizes offered for four plants, and Mr. Williams was deservedly placed first for capital examples of *Kentia australis*, *Cocos Weddelliana*, and *Latania borbonica*. Mr. Roberts secured the second award. For four *Yuccas*, not less than two kinds, Messrs. A. Cole, R. Elphinstone, and G. Kemp were the

successful competitors in the order named, the several exhibits being highly satisfactory.

**ERICAS.**—These plants were not very largely shown, but the first prize collection of Mr. J. Cypher for six plants contained some remarkably well-flowered plants of *E. Cavendishiana*, *E. depressa*, *E. ventricosa hirsuta alba*. In the amateurs' class for the same number of plants Mr. A. Cole took the lead with capital plants, well flowered and healthy, but rather uneven in size. His best were *E. Cavendishiana*, *E. ventricosa coccinea minor*, *E. v. tricolor*, *E. v. alba tincta*, and *E. splendida*. Mr. G. Williams was second with smaller examples, and Mr. J. F. Mould third. *Azaleas* need no special note, for those staged for the prizes offered were of poor quality.

**FERNS.**—The class for eight stove and greenhouse Ferns was well represented, and some excellent specimens were staged. Mr. G. Paul took the lead with remarkably large plants fully 7 feet through of *Gleichenia Mendelii*, *Gleichenia Speluncæ*, *G. rupestris glauca*, and *G. flabellata*; *Goniophlebium subauriculatum* was a magnificent plant, and also *Dicksonia antarctica*, *Alsophila Williamsi*, and *Cibotium regale*. Mr. Hesketh, gardener to A. Birley, Esq., was a good second, and Mr. W. Plant, gardener to R. P. Gill, Esq., third. In the open class for twelve hardy varieties, Mr. C. Rylance, nurseryman, Aughton, was well to the front with large handsome plants of *Athyrium F.-f. plumosum*, *A. F.-f. Craigi*, *A. F.-f. Fortitæ*, *A. F.-f. corymbiferum*, *A. F.-f. Fieldiæ*, *Lastrea F.-m. cristata angustata*, *L. F.-m. grandiceps*, *Polystichum proliferum*, and *Athyrium F.-f. Vernoniæ*. Messrs. W. & J. Birkenhead, Sale, Manchester, were second with a superb collection of Ferns. Amongst the most striking were *Osmunda regalis cristata*, *Adiantum pedatum*, good; and *Polystichum angulare plumosum*. Mr. J. Hesketh was placed third, and also staged good plants, having very fine *Athyrium F.-f. Fieldiæ* and *A. F.-f. Craigi*. In the amateurs' class for the same number of plants, Mr. T. Tyldesley, Worsley, was a good first with good examples of *Athyrium F.-f. todeoides*, *Athyrium F.-f. acrocladon*, *Lastrea F.-m. grandiceps*, and others, the same as named in the open class. Mr. Broadman, gardener to Mrs. Hodgkinson, Bowden, was a close second, and Mr. F. W. Stansfield, Sale, third.

**GLOXINIAS.**—On the whole these were good. The plants were not large, but fresh and profusely flowered. For ten plants Mr. G. Worthington, gardener to A. Ward, Esq., Didsbury, was first; and Mr. J. Eden, gardener to Mrs. C. Sergeant, Sale, second; these being scarcely so large as the first prize collection.

**CLEMATISES.**—These plants were not well represented in the class provided for them, and only one collection was staged by Mr. Bennett, gardener to T. Dickens, Esq., Higher Broughton. This collection was well grown and profusely flowered, and well deserved the first prize accorded to them.

**CALCEOLARIAS.**—It is very seldom that finer or better-grown specimens are staged than the first prize collection staged by Mr. R. Elphinstone in the class for eight plants. The plants were from 2 to 3 feet through them, and did not exceed 18 inches in height. Second Mr. T. Grosvenor, gardener to A. W. Bradley, Esq., Congleton. Third Mr. G. Worthington, gardener to Z. A. Ward, Esq., Didsbury.

**NEPENTHES AND SARRACENIAS.**—These were remarkably fine, and the competition very good in the two classes devoted to these plants. For ten plants in the open class Mr. H. James was first with a capital assortment, followed by Mr. A. J. A. Bruce, Chorlton; and Mr. J. F. Mould, who staged healthy but rather small plants. In the amateurs' class for the best collection Mr. A. Cole was well to the fore with the finest collection in the Exhibition, and comprised grand plants of *Nepenthes Broomiana* with large dark patches, *N. Hookeri*, *N. Henryana*, *N. Mastersiana*, very fine; *Cephalotus follicularis* was very fine, so also were *Sarracenia Swainiana*, *S. Chelsoni* very good, *S. illustrata*, *S. flava*, *S. maxima*, and *S. Mitchelliana*. Mr. J. Morton, gardener to J. Feides, Esq., second with a very good collection, but smaller than the preceding.

**PELARGONIUMS.**—For eight show varieties Mr. C. Rylance was the only exhibitor, and staged very fresh, large, neatly trained plants of *Prince Leopold*, *Madame Hilliard*, *Kingston Beauty*, *Edward Perkins*, *Duke of Edinburgh*, *Queen Bess*, and *Venus*. Mr. Rylance was the only exhibitor in the corresponding class for eight fancy varieties. These plants were remarkably good, being very fresh. The best were *Duke of Edinburgh*, *Exquisite*, *Evening Star*, *Helen Beck*, *Sarah Turner*, and *Barbet*.

**ROSES IN POTS.**—In the nurserymen's class for thirty plants in any size pots, including standards arranged in a group, Messrs. Paul & Son, Cheshunt, secured the premier position with a number of standards arranged in the centre, and dwarfs round them, with a groundwork of *Adiantum cuneatum*. The effect of this arrangement was all that could be desired. The standards had even-sized heads, and comprised the following:—*Alfred Colomb*, *Niphetos*, *Innocente Pirola*, *Celine Forestier*, *Madame Cusin*, *Anna Olivier*, *Catherine Mermet*, *Centifolia Rosea*, and *La France*. The best of the dwarfs were *Madame Victor Verdier*, *Duke of Teck*, *Souvenir d'un Ami*, *Benoit Comte*, very bright; *Madame Lacharme*, *Etoile de Lyon*, *François Levet*, *Souvenir de Thérèse Levet*, and *Alba Rosea*. Mr. J. F. Mould was placed second with a very creditable collection. For twenty plants in pots not more than 9 inches in diameter Messrs. Paul & Son, Old Nurseries, Cheshunt, secured the first award, and Mr. J. Harley, nurseryman, Stockport, the second, both staging well-flowered fresh examples. For six plants (amateurs) J. Brown, Esq., Heaton Mersey, was a capital first, and staged fine plants of *La France*, *Paul Ricaut*, *Madame Lacharme*, and *Madame Willermoz*; second Mr. Bennett, gardener to T. Dickens, Esq.; and third Mr. R. Elphinstone, both showing well. Mr. Bennett was awarded an extra prize for a group of Roses not for competition.

**PANSIES AND VIOLAS.**—The pots of these were particularly fine this year, and occupied nearly the whole side of one of the large tents. In the six classes devoted to them the competition was very good, and in many instances very close. In the open class for twenty fancy varieties Mr. S. Robinson, Sale, took the lead with a capital lot, followed closely by Messrs. E. Mellor and J. Heywood. For the same number of Pansies Messrs. E. Mellor and J. Heywood again took the lead in the order named. For twenty Violas, Mr. John Heywood, nurseryman, was first, Mr. J. Mellor, Didsbury, second, and Eliza Mellor third. In the amateurs' class for six pots Mr. G. Wilkes took the lead. For six Fancies Messrs. G. Wilkes, gardener to S. Lord, Esq., and Mr. J. Eden were the prizetakers. For six Violas Mr. W. Rose, gardener to D. McClure, Esq., Heaton Mersey, first with fine pots, second Mr. G. Wilkes, and third Mr. J. Eden.

**HERBACEOUS AND ALPINE PLANTS.**—These have never before been staged in such large numbers or in such admirable condition. With the Orchids they certainly were the great features of the Exhibition. If the whole of these plants had been grouped together in one of the large tents they would have more than filled it. In the nurserymen's class for sixty herbaceous and bulbous plants only one exhibitor staged plants—namely, Messrs. James Dickson & Sons, Newton Nurseries, Chester, for which the first award was made. This collection was the admiration of all, and consisted of large well-developed plants of *Gladiolus Ardens*, pure white, rosy spots, very fine; *Blushing Bride*, another fine form; *The Bride* was also well done; *Pæonia sinensis Virginie*, P. s. Paganini, P. Pottsi fl. pl., P. s. odorata were all good and well flowered. *Delphinium Mrs. Mary Russell* and *D. Wilsoni* were attractive and showy. *Liliums* were very good, especially *L. longifolium*, *L. giganteum*, *L. testaceum*, *L. Browni*, *L. Harrisii*, *L. davuricum grandiflorum*, *L. tigrinum*, and *L. caudatum*. *Carnations* *Gloire de Nancy* and the old *Crimson Glove* were striking, while *Phloxes* *Mrs. Hunter* and *Mrs. James Ross* were very effective. *Campanulas* were good, especially such as *C. azurea*, *C. Van Houttei*, and *C. persicifolia fl.-pl.*, *Lupinus polyphyllus albus* and its light blue form were most striking. *Anthericum liliastrium* was very good, and also several German Iris. *Dianthus magnificus* was particularly fine, and the same may be said of *Centaurea rubra* and *Pyrethrum Madame Baltet*. In the corresponding class for an unlimited collection of plants the same exhibitor again secured the highest honours. There was no competition in this class, but the group under notice could not well have been excelled. It contained no less than 100 different varieties, and the whole were healthy, in full flower, and most effectively arranged. These two groups were arranged in the large tent on the ground opposite each other, and were undoubtedly the most attractive feature of this tent. In the same division of the schedule, Messrs. F. W. & H. Stansfield, nurserymen, Sale, were well to the front for forty Alpines in or out of flower. The collection was neat and very effective. Mr. James Mellor, Didsbury, was second, and Messrs. Paul & Son, Cheshunt, third; Messrs. James Dickson & Sons being awarded an extra prize for their collection in this class. At first sight this collection appeared the most showy, but upon examination it could readily be seen that the plants had been somewhat unduly forced or retarded too long. The four collections were, however, wonderfully fine. In the amateurs' class for thirty herbaceous and bulbous plants, Mr. W. Plant was well ahead with a grand assortment of well-grown plants. In this collection it may be noticed the clumps of plants were naturally grown. For instance, the pan of *Saxifraga pyramidalis* had not had flowering crowns only selected in making up the specimens, as was the case in others. Some of the most noteworthy plants in this collection were *Spiræa Aruncus*, *Spiræa palmata* with forty-three flowers (very fine), *Anthericum liliastrium*, *Aquilegia chrysantha*, *Cypripedium spectabile*, *Erigeron speciosus*, *Centaurea montana rubra*, *Phlox grandis*, *Phlox Countess of Horn*. Mr. A. Cole was a good second, and Mr. T. Dickens, gardener to H. Bennett, Esq., Higher Broughton, a good third. For thirty Alpine plants, Mr. A. Cole took the lead with a choice and well-grown collection; Mr. E. Wright second, and Mr. W. Plant the remaining award. For twelve plants, Mr. A. Cole was again first, Mr. R. Tyldesley second, and Mr. E. Wright third.

**CUT FLOWERS.**—These were not numerous, and consisted entirely of Roses, which were very praiseworthy considering the time of the year. In the amateurs' class for twelve Tea varieties T. B. Hall, Esq., Rock Ferry, was deservedly placed first with a stand of grand well developed blooms of *Alba Rosea*, *Niphetos*, *Madame Margottin*, *Souvenir d'un Ami*, *Madame Willermoz*, *Innocente Pirola*, *Anna Olivier*, *Francisca Kruger*, and *Madame Cusin*. For eighteen Tea blooms in the nurserymen's class Messrs. G. Paul and Son were placed first, this being the only exhibit. This collection contained good blooms of *Maréchal Niel*, *Niphetos*, *Souvenir d'un Ami*, *Comtesse de Nadaillac*, *Alba Rosea*, and *Francisca Kruger*, very fine. For twelve blooms, others than Tea kind, Mr. J. Grier, gardener to J. Brown Esq., was the only exhibitor who staged very creditable blooms, to which the first prize was accorded.

**FRUIT.**—The display of fruit was good considering the season, and the exhibits were not only much more numerous but of better quality than on past occasions. For a collection of eight dishes, distinct kinds, Mr. G. T. Miles, gardener to Earl of Carrington, Wycombe Abbey, was awarded the post of honour. This collection contained excellent examples of Foster's Seedling and Black Hamburgh Grapes, a Queen Pine, Longleaf Perfection Melon, good; Stirling Castle Peaches, Lord Napier Nectarines, large and splendidly coloured; Black Caucasian Cherries, and Dr. Morie Strawberries, very fair. Mr. J. McIndoe, gardener to Sir J. W. Pease, Bart., Hutton Hall, a good second, with Best of All Melon, Muscat of Alexandria Grapes, very good for the time of year; fair Black Hamburghs, good Barrington Peaches, and Brown Turkey Figs. Mr. R. Davies, gardener to Hon. Mrs. Meynel Ingram, Temple Newsham, the remaining prize, and had good Queen Pine, Black Hamburgh Grapes, and La Grosse Sucrée Strawberries. For two bunches of black Grapes several competitors staged excellent fruit. Mr. J. Hollingsworth, gardener to J. F. Campbell, Esq., Woodseat, Uttoxeter, was placed first with two perfect bunches as regards colour and size of berry, the bunches being smaller than the second prize exhibit, contributed by Mr. J. Lowden, gardener to T. Barnes, Esq., The Quinta, Chirk. These bunches were large and the berries good, but the points of the bunches were a little deficient in colour. Mr. J. McIndoe received the remaining award with moderate sized bunches well finished, but the berries were under-sized. For two bunches of white Grapes Mr. G. T. Miles took the lead with capital examples of Buckland Sweetwater; Mr. J. Breese, gardener to Mrs. Ackers, Congleton, second with Duke of Buccleuch; and W. Bretherton, Esq., Exton, Chorley, third with Foster's Seedling. For two Pines Mr. H. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Derby, and Mr. J. McIndoe were the prizetakers, being awarded second and third, the first prize being withheld. The fruit in the corresponding class for one dish was very poor. For one dish of Peaches the competition was very good, and some excellent well-coloured fruit was staged. Mr. W. Elphinstone, gardener to E. M. Mundy, Esq., Shipley Hall, Derby, was placed first with very fine fruit of Royal George, Mr. J. Wallis, Keele Hall, second with Hale's Early, and Mr. G. T. Miles third. For one dish of Nectarines the last named exhibitor was placed first with a grand dish of Lord Napier. Mr. J. Bannerman, gardener

to Lord Bagot, second with the same variety, and Mr. McIndoe third, also staging the same. For one scarlet-fleshed Melon a good number of fruit were exhibited. Mr. G. T. Miles was first with a handsome fruit of Scarlet Hybrid. Mr. McIndoe followed with Scarlet Premier, and Mr. J. Hare, gardener to R. H. C. Neville, Esq., Grantham, third with a seedling. For one green-fleshed kind an equal number of fruits were staged. Mr. G. T. Miles was successful with Burghley Pet, Mr. Hare second with Dell's Hybrid, and Mr. McIndoe third with Best of All. For one dish of Cherries some really fine fruit was staged. Mr. Hare took the lead with Black Tartarian, followed by Mr. Miles with Elton. For one dish of Strawberries some very large fine fruit was staged. Mr. P. Paine, gardener to Captain Dixon, Chelford, was deservedly placed first with handsome large fruit of President. Mr. R. Davies second with La Grosse Sucrée, and Mr. Miles third with Sir Joseph Paxton. Strawberries in pots were wonderfully fine, especially the twelve pots staged by Mr. G. Malcolm, gardener to J. Tomkinson, Esq., the variety being Cambrian, and most of the plants carried over twenty large fruits, some of them from twenty-five to thirty. Mr. R. Davies was placed second with a creditable collection, and Mr. W. B. Upjohn, gardener to the Earl of Ellesmere, Worsley Hall, third.

**MISCELLANEOUS EXHIBITS.**—These were very numerous, and added materially to the beauty of the Exhibition. In the large exhibition house Mr. B. S. Williams contributed a very large collection of decorative, flowering, and foliage, including many Orchids in small pots amongst the former. This was a very striking and effective group of plants. Messrs. Sander and Co. contributed a collection of various Orchids in flower in from 5 to 7-inch pots, effectively arranged with *Adiantum cuneatum*. The Horticultural Company (John Cowan), Garston, Liverpool, contributed a similar group, but Dendrobiums predominated, while Cattleyas and Odontoglossums were the leading feature of the former group. Messrs. R. P. Ker & Sons staged a choice collection of Crotons, Dracaenas, interspersed with Palms and Ferns and small decorative flowering plants. Messrs. W. & J. Birkenhead added to the Exhibition by a collection of hardy and exotic Ferns in good condition and variety. Messrs. W. Catbush & Sons, Highgate, London, had a very large collection of Ericas, Pimeleas, and other hard-wooded plants, with Palms, Ferns, and other foliage plants freely intermixed. Messrs. R. Smith & Co., St. John's, Worcester, staged Clematis, large trained plants, amongst them being their new bedding variety, which appears to produce both single and double flowers. This is named Beauty of Worcester. The most effective and interesting portion of this group being a large number of Clematis in 4-inch pots, producing one or two large flowers each, and not more than 1 foot to 18 inches high. Mr. B. S. Williams also staged two fruits of his new Melon Harefield Grove, which has a good appearance, and resembles Cox's Golden Gem. Messrs. Dickson, Brown, & Tait staged a large fruit of a Melon named Penrhyn Seedling, which received a certificate at this Society's Show last year. It is a large fruit, said to weigh from 4 to 9 lbs., and to be ten days earlier than Cox's Golden Gem, which is one of its parents. Both the flavour and appearance are good, and the Judges awarded it a first-class certificate. Mr. B. S. Williams also staged a dish of fine fruit of his new Tomato Harefield Golden Gem. Mr. S. Robinson, florist, Sale, contributed large boxes of *Anthericum liliatum*, and Mrs. Eliza Mellor a collection of alpinas; Messrs. J. Waterer & Sons a large collection of Acers and Rhododendrons, also Golden Queen Hollies, but these were arranged at the entrance of the tents; Mr. J. Hcoley, Edgely Road, Stockport, contributed a large collection of Hollies, Conifers, and Rhododendrons. The two groups to the entrance of the large tent from this firm were very effective. Messrs. Backhouse & Sons of York added wonderfully to the interest of the tent in which the alpinas were arranged by a large, varied, and interesting collection of these plants, and for which the Society's silver medal was deservedly awarded. Mr. G. W. Yates, Eaton Norris, Manchester, also staged effective groups of Rhododendrons.

### STRAWBERRIES AFTER FORCING.

STRAWBERRY forcing is now over. As a rule the plants are turned out in frames or into the open air after all the fruit has been gathered from them, and they often remain until they are covered with insects, which take possession of other plants, and mischief follows. It is generally intended to do something with the Strawberry plants—plant them out to fruit in the autumn or to secure early runners from them—but they are more often neglected and allowed to become so dry at the root as to become a pest as suggested, then they are thrown away. I am not in favour of retaining Strawberry plants for any purpose. I have tried the planting out with various objects in view, but with no advantage. I have also seen large quantities planted out, but never learned of satisfactory results. Plants which fruit again in autumn are few, and as for supplying early runners, any good plantation will do this as early as they are wanted. As soon as our Strawberry plants have given up their crop they are at once thrown away, and the space they occupied, as well as the pots they were in, are filled with more profitable crops than the old plants. We secure our earliest runners from plantations in the kitchen garden from the middle to the end of June; the plants have then four months in which to grow and mature, and they are equally as good and satisfactory as any from old pot plants.—A GARDENER.

### ARAUCARIA IMBRICATA.

In my garden there is an Araucaria which has been planted about twenty years. It is about 20 feet high, 15 feet bough from bough, and grown very evenly from top to bottom; but what I believe is not a common thing is that it is bearing "cones" or seed. I enclose you photo of the tree, but as it is only taken by an amateur it is not very good. Any information you can give me in the matter I should be glad to receive. The tree can be seen at any time at Woodlands, Black Fen, near Eltham, Kent.—W. P. SANDERSON.

[We are obliged for the photo, but a much finer specimen, from

Veitch's "Manual of the Coniferae," was represented in our columns in 1881, page 171, volume ix., New Series. See answer to a correspondent on another page.]

### FORCING VIOLETS.

FORCING, though a term sometimes applied to Violets, is hardly applicable, as with a proper preparation and treatment of the plants bloom can hardly fail to be forthcoming in due season, or from September to April, or a month earlier or later according to the season or variety. We have gathered Violet flowers in every month of the year, but they are not of so much account after Pinks, Cloves, and other Carnations with Roses become plentiful, and to have Violets in season, or from September to April inclusive, is one of their greatest charms—viz., their great continuance, value being estimated by what is liked best and enjoyed longest. Violets yield to no other flower in that respect, and meet the requirements of all classes.

To force Violets it is essential that they be grown as advised for those in frames, and that they be established in frames, pits, or pots. If in pits there is no difficulty in keeping up a supply of flowers with a number of plants adequate to the demand for flowers, and the means of affording heat so as to insure flowers independent of the weather. A high temperature is not necessary; air is highly important, in fact the most important element in Violet culture, and moisture is equally essential. Air, moisture, and sufficient warmth to insure the development of the blooms is all that is required, with all the light practicable. Air constantly, and a temperature of 50° artificially, is ample. A higher temperature from sun heat will not matter provided it be accompanied by an increase of ventilation, and at night 40° to 45°. Higher temperatures elongate the leaves and flower stems unduly, and give them a weak, attenuated, and unpleasant appearance.

Plants in pots are easily brought into flower placed on shelves, or preferably on a damp base, as that of cocoa-nut refuse or ashes kept wet, and well up to the glass in a light airy house in which a temperature of 45° to 50° by artificial means is secured, and advancing to 65° from sun heat with abundance of air. A succession of fresh plants introduced at intervals in accordance with the demand of individual establishments will insure an unbroken supply, the plants being drafted from cold frames protected in severe weather, so as to be always available for the purpose at fortnightly intervals, or as required.

Everyone has not command of a greenhouse or forcing house. The best way to have Violets in such cases is to grow the plants in frames, they having been grown for the purpose in the open ground in summer. A warm sunny situation should be chosen for the frame, and a foundation of faggots formed for it to stand on, so that the heat of the materials employed may pass under the bed by the faggots, the heat being afforded by fermenting materials in the form of linings, in which way it can be added to or renewed according to the state of the weather. The faggots should form a base cross-wise to the frame of about 2 feet high, and the exact size or a little more than the frame. A layer of rather rough spent litter should be placed on the faggots about 6 inches thick, and then the frame on that. Put in a layer of leaf soil or well decayed manure 3 inches thick, and then the compost for packing the plants as indicated in the article on "Violets in Frames." The plants should be put in their forcing quarters by the end of September, and kept duly supplied with water. The lights need not be used until frost, and by the time growth is stayed naturally artificial means must be set to work to maintain it. This may occur early in November, but by the middle of that month sufficient tree leaves with a fourth part of stable litter should be mixed and placed loosely all round the bed and to the height of the base of the frame, and these can be made firm and added to as the heat becomes necessary, there being no difficulty in regulating it to the greatest nicety by turning one or more of the linings, and adding fresh material at any time, and the warmth will pass into the faggots, diffusing itself through them, and being absorbed by the bed over them. The Violet roots soon feel the warmth, the impetus given them is transmitted to the flower buds and flowers, and the flowers come unusually fine and over a lengthened period. Air must be admitted freely on all favourable occasions, and a little air admitted constantly by tilting the lights at back will allow of superfluous moisture escaping. Avoid cold currents of air, as it chills and stunts the expanding flowers, but a close atmosphere must be avoided, and though protection over the lights will be necessary in very severe weather it must not remain on longer than is absolutely necessary. Sharp frosts, sudden heats, close confinement, and inattention ruin Violets.

The best varieties for forcing are the Neapolitan varieties:—New York, Marie Louise, De Parme, White Neapolitan, and old Neapolitan.

*Growing Violets in Moss for Filling Flower Boxes, Table Decorations, &c.*—Large plants may be had by lifting well-grown plants carefully and removing all the soil from the roots. If it adheres very closely to them wash it off. Remove any bad leaves, and with some wood moss freed from leaves, sticks, and rubbish, and washed clean, take a handful of charcoal and wrap it in a little moss. Take the plant in the left hand, and plant so that the roots will spread evenly over the ball of charcoal and moss, forming into a ball, and cover the roots neatly with moss, and secure with fine galvanised wire. Immerse in water, and pack in boxes of about 3 inches depth, with holes at bottom to allow superfluous moisture to drain off. The plants can be placed either in the boxes or close together on slate shelves in a house with a temperature of 40° to 45° at night, and 50° by day artificially, and sprinkled each morning, they will soon be sufficiently advanced for use in the house. Such, from their less weight, are much better than plants lifted with balls of earth and mossed,

in which way, however, they answer very well. Care should be taken to keep the moss thoroughly moist. Weak liquid manure in a clear state and tepid may be given whenever water is required by immersing the mossed balls of roots.

Small plants for table and other decorative work can be had by layering the runners in the summer as advised for Violets in pots. These lifted in autumn, the soil washed away, a piece of charcoal wrapped in a little moss, the roots spread over it, covered with moss, and secured with wire, may be treated as advised for the larger plants. When furnished with fresh leaves and flowers they are charming for decorative purposes. The system is applicable to all kinds of Violets, but the best are Russian, Floribunda (Boothby), Victoria Regina, White Czar, and argenteaeflora, with Odoratissima of the single varieties. Of the doubles, Patrie, and Double Russian of the dark blues; of Neapolitan vars. New York, De Parme, and White Neapolitan.

**Securing Violets in Winter by other Means.**—Plants lifted in autumn with balls of earth, and planted in the borders of fruit or plant houses, which, though unsuitable for growing the plants, will by the shelter and immunity from frost have the flowering accelerated. They may be packed in leaf soil on the border with a board or boards on edge supported by pegs driven in the border. Peach houses and orchard houses may be named as suitable structures for Violets, but any houses from which frost is excluded but otherwise kept cool are suitable. Plants in flower may also be had by lifting with roots and packing them in boxes in leaf soil, and placing in frames, or houses where there is a gentle heat well up to the light, from which they can be withdrawn when in flower, mossed, and used for mixing with other subjects in house decoration.

Plants can also be lifted and placed at the foot of walls or fences with a south aspect, planting in leaf soil well mixed with the soil, and giving a good watering to settle the soil about the roots. They may be covered with handlights, and given air on all favourable occasions, and protection given in severe weather, some useful sweet flowers will be obtainable when there are few or none other to gladden sight and sense. Plants placed at the foot of walls or fences with a warm aspect will come in much in advance of those in the open, and in the case of Neapolitans they may survive when those in the open are too much damaged to give flowers of value or any at all through frost, which is very destructive of Violets, especially in low or flat localities inland. Violets like hills and sea breezes, in fact warmth without air is positively ruinous, and equally disastrous is drought; therefore, plants in front of walls must have the soil kept moist, and no coddling allowed under any circumstances.

**PROPAGATING VIOLETS.**—Violets are increased by seed, some coming true, which more particularly applies to the species, garden varieties being very sportive when raised from seed; by runners, suckers, and cuttings.

**Seed.**—Flowers fertilised in spring ripen the capsules of seed in summer or autumn, but some autumn flowers ripen the seed pods in spring. Only the single varieties seed. Some of the semi-double varieties, however, afford seed sparingly, as *Parmænsis plena* and White Neapolitan. The seed should be gathered before the capsules burst, which may be ascertained when about to take place by the changed colour of the seed pods, they becoming much paler or a creamy white. Laid on a sheet of paper or on shelves they soon shed the seeds, if kept dry and cool. They may be sown as soon as ripe in beds outdoors, and covered about a quarter of an inch deep with fine soil. If sown early in autumn or early in September they will germinate at once, and in that case are best sown in cold frames, in pans, or boxes. They should be kept moist, well up to the glass, and ventilated freely on all favourable occasions. In spring, when well hardened, plant in lines 18 inches apart and 1 foot asunder in the rows. This is for garden varieties of Czar, which is a seedling of Giant, and Giant a seedling of the Russian, but species need only have the rows 12 inches or 15 inches apart, and 3 inches less in the rows. Well attended to they will flower the ensuing season.

Spring is, however, the best time to sow Violet seed, it being kept cool and dry over the winter, or it may be sown in autumn, in which case the plants usually do not appear until the following spring. March is a good time to sow the seed. The seed should be scattered thinly. When the plants show the second leaves prick them off about 3 inches apart, water, and shade until established. Transplant to their flowering quarters before they become crowded, duly attending with water, &c. The strongest will flower the following season, but some will need to remain another year and be treated as established plants before they flower in character; indeed, they ought to be kept a year after they flower if at all worthy, as the first blooms are not nearly so good on the seedling as those borne by the parent subjected to cultivation by its suckers or runners. Tender varieties should be wintered in frames. Except for the raising of improved varieties the raising of Violets from seed is not advisable, as they are not so floriferous and do not afford such fine blooms as plants from suckers or runners. By selecting plants that show improvement in the blooms and saving seed from them, much further progress can be made; but taking Princess of Prussia (Lee) as a fair example of what a Violet should be, or even Odoratissima (Lee), very few seedlings indeed pass muster, and such only are worth continuance.

**Runners.**—Strong plants put out in April afford runners through the summer freely. When they show the plant at the end of the runner wire they may be layered in pots, and secured with pegs made of No. 14 galvanised wire cut into lengths of about 3 inches and doubled like a hair pin, having about half an inch space between the wire. The runners may also be layered in the soil, and kept moist they will soon root, about an inch of the runner wire being inserted in the soil and secured with a peg. When rooted, detach them and plant them in nursery beds in rows about 6 inches apart and 4 inches asunder in the rows. Early runners will

require more distance. Very late runners may remain on the plants until planting time in spring. Early runners in pots should be stood on a north border for a few days after being detached, and when recovered potted in 5-inch pots and grown on in the open. They give some very fine flowers in winter treated as pot plants. Small varieties should only be given 4-inch pots. Runners are the very best for making fresh plantations, being preferable to suckers.

**Suckers.**—There are most generally used for making fresh beds. They come from the stem below ground, and are detached in spring, and usually have roots. Some varieties have few offsets or suckers, most after a stock is formed afford sufficient for general purposes of increase; but though a ready means of maintaining the stock, it is not so good as the despised method of following Nature, simply because it is handy and entails less trouble. Suckers are very often weak and drawn from being overshadowed by the parent, and they sometimes so feel the loss of the shelter as to take very badly to their new quarters, being much affected by the exposed situation, going back instead of forward.

**Cuttings.**—These are of two kinds—viz., rootless runners and rootless offsets or side growths. Rootless runners are common in spring on Neapolitan varieties. These detached in February or early March with about 2 inches of the runner wire, and cut transversely below a joint if there be one about that length, a little more or less not making much matter, from the runner plant or leaves at the end of the runners, and dibbled around the sides of pots, or in pans about 1½ inch apart in light loam and leaf soil in equal parts, with a sixth of sand, inserting them up to the leaves, and if placed in gentle heat, kept moist and shaded, they soon form roots. When hardened they can be pricked off in cold frames, and grown on preparatory to planting out in late April or early May. Late runners may be rooted in a similar manner, or kept over the winter in the cutting pots in cold frames they will root slowly but surely, being kept moist, plunged, and protected in severe weather.

Cuttings of the tops or side growths root freely in gentle heat at any time, but preferably in September and March. Growths with an inch or two of stem and the crown or growing point are suitable, trimming off the leaves with a sharp knife, leaving those at the crown intact, and cutting transversely below a joint, insert up to the centre leaves, leaving them just clear of the soil. They strike equally well in a cold frame, but take a longer time. This method is available for varieties that do not afford runners freely, but the plants are not nearly so strong and healthy, being very liable to lose the centre or crown. Cuttings or runners should always be taken from healthy floriferous plants with flowers large in size and of fine form.—VIOLETA.

## RED SPIDER ON MELONS.

WE have always been of opinion that, next to the destruction of the mealy bug on stove plants, that of the red spider on Melons is a subject of great difficulty. The golden rule is, in both cases—Try to keep the vermin away; as though certain extreme measures will annihilate both these pests, yet their destruction is rarely accomplished without that amount of injury to the plant which makes the cure worse than the disease. Nevertheless, as something must be done to save a crop of Melons, which the amateur prided himself upon as likely to produce something valuable, and which, hitherto, looked every way promising, when lo! he is astonished or alarmed at seeing a few of the large leaves in the centre of the plant look rather brown or yellow; and, on turning them up, he sees a thin film of spider-work stretching between the ribs and other portions of the leaf, and, to the naked eye, minute insects of a brownish red colour may be seen nestled here and there amongst the network, which they have drawn over their workings. This latter pest, whose powers of production would seem to set all calculation at defiance, exists in such a multitude of plants of various habits, that it may almost be called universal. A gentleman told me that he has discovered it on the leafless succulent plants of the Cactus family; and we all know how much field Turnips are affected with it in hot seasons; and trees innumerable, down to the very Box edging which margins our walks, being, in certain seasons, a martyr to it. Now, when we see it living and thriving on the hard leaf of Box, how much more likely is it to take up its abode and multiply on the more delicate foliage of an annual plant so tender as the Melon; so that we may fairly inquire if a perfect remedy be not an unsolved problem? Nevertheless, we are far from giving it up, and as we have had much experience in the matter, we will give the result, with now and then a suggestion to meet individual cases, beginning first with what we suppose to be the causes which favour its first attack.

We are led to believe that the larvæ of this insect either lurk in the frame, or are carried thither by the winds, or some other of those agents which tend to multiply the species of the lower orders of vegetation, as well as of animals; our first duty is, therefore, to check that if we can, on the good old golden precept that "prevention is better than cure." Washing well the lights and ratters is attended with benefit, and the same to the interior of the box or pit, with all its fittings; after which the latter ought to be whitewashed with a compound in which lime and sulphur were mixed, with perhaps a little cow dung to make it adhesive. Bright sunny weather following after the plants have grown so as almost to occupy the whole of the frame, daily watering about four o'clock in the afternoon, and shutting up for the evening, will be of great service in preventing this pest, much more so than dusting with sulphur; this however, cannot well be adopted in all cases with those kinds called "difficult setters," consequently, while that process is in operation, the

frame must be kept more dry. If red spider attacks the plants at this early stage, we fear all the assistance in the universe will hardly insure a good crop; but we will suppose them to have prospered so far, that a fair crop of fruit, half swelled or more, is for the first time noticed to be attacked, and then the question is—what remedy to apply? Water is found unable to stay the ravages of the little marauders, and some other auxiliary must be put in force; one of the best is partial shading. For that purpose a slight colouring the glass with limewash is useful; if this be used, let it be done outside, as it does not easily wash off with rain, and leaves so gradually, that the loss is imperceptible; flour and water adhere less firmly to the glass, and ought to be applied inside. This shading being more congenial to the welfare of the plants than to the insects, enables the former to advance, not so fast, certainly, as when enjoying the full amount of unobstructed sunshine, yet sufficiently so as to leave their enemies in the rear.

Perhaps, however, this remedy is insufficient, and the enemy keeps advancing; some other means must be adopted. Now we have heard some recommend watering with soapsuds as a cure, but somehow we never derived the benefit from that plan commensurate with the mischief it occasioned. Soapsuds usually leave a coating on the leaves of plants of a thick glutinous matter, which, in point of substance, very much resembles paint, and is scarcely less difficult to remove. It is therefore injurious to the delicate foliage of the Melon, rendering them all but useless for the purposes intended. Their numerous pores being all but sealed up, they languish and die. Dabbing on soapy lather is only another mode of effecting the same object, that unless assiduous waterings at the proper times and shading as above be able to combat the evil, recourse must be had to that all-important insect killer sulphur, which, however, must not be applied in dusting the leaves, but in placing it in such a manner that its fumes will act on the insect without its coming in immediate contact with the plant. Now in a pit heated by hot water this object is easily effected, as scattering some along the heating contrivances effects the purpose at once. Not so, however, the common dung frame, in which the great mass of Melons grown in the summer months are produced. Here something on which the warmth of the sun may act must be put in requisition; for that purpose paint the inside of the box with a mixture of clay and sulphur, the former is simply to give it substance so as to adhere, for which anything else may be substituted.

In addition to this, paint a few pieces of slate, tiles, or small pieces of board in the same way; these pieces lay carefully under the parts of the plant most affected, and the sun acting on them occasions their emitting that vapour so obnoxious to this insect, as it is well known that it is only the gas generated by this substance becoming warmed, to a certain extent, that proves fatal to this and other members of the lower creation, that we regard it almost innocuous at a low temperature; in other words, we think its utility is increased the more we can smell it, which everyone knows is most done in a bright sunny day, or when subject to fire heat in some shape. As we have used these painted slates with success, we strongly urge on the amateur, whose plants are threatened with red spider, to think of that in time. Remember, we only advise their adoption when plain, clean, soft water has failed to stay the progress, or effect a cure, while he may apply both remedies at the same time; the coloured slates by day, and watering all over at nights, taking care to remove the slates when he waters, which, however, is quickly done. We will not affirm that he will be able to restore plants once attacked to the condition of those never so afflicted, but probably he will be able to maintain them in sufficient health to ripen the crop; the latter part of which time he ought to be very careful in giving no more water than just sufficient to maintain the foliage in health.—R. J. O.

#### IVY-LEAF PELARGONIUMS.

We are cutting trusses of the best double varieties now, and from the extreme beauty of the flowers, combined with adaptability as decorative plants—features which are as yet comparatively unknown—I am induced to send this note in their favour. The plants are easy of culture, provided their requirements are understood and supplied; the chief point in which beginners are likely to make a mistake being giving too little heat, at least early in the season. My experience with them is that they require to be kept warmer than the single varieties in order to insure plenty of flowers over a lengthened period.

The best time to propagate is the present for strong early-flowering plants, and in August for plants to come on later in the season. I like strong cuttings rather hardened at the base than soft. One cutting is put into a thumb pot filled with light soil, and the pots are placed in a warm pit until a fair number of roots have been made. During the summer months a cold frame suits them well. The attention they require is first to shift them out of the cutting pots when thoroughly well rooted, and potting into 4½ or 5-inch pots. The soil I use is a turfy loam enriched with cowdung. The pots are well drained, and in potting the soil is made firm. This potting will carry the plants over the winter. Then they will require pinching at least twice—the stronger plants before potting, any others after they have become established. About the middle of September the plants are pinched the second time. An occasional surface dressing of an artificial manure being of much benefit to the plants, and may be applied about once in three weeks from the end of August. Stake as required. The plants should be kept growing throughout the winter months, and if properly managed will require a slight dressing of manure at intervals, as above stated, right on until February, when they are ready to be transferred into 7 or 8-inch pots. A couple of months' further attention to pinching, staking, watering, and

keeping the plants in a growing temperature will have secured fine strong plants full of flower. During summer manure should be applied in weekly dressings, straggling shoots pinched and tied to sticks, and the trusses removed as they open fully, or as wanted. August cuttings are harder than those which can be had now; moreover, they can be cut much longer, and the foundation of a strong plant is more easily secured. The cuttings strike well, several in one 6-inch pot filled with light soil, or they may be put singly into 2½-inch pots and wintered therein. In any case it will be found that the cuttings will strike most steadily if they are placed under glass—such, for instance, as an early vinery. During winter do not allow the plants to stagnate in a cold house, but keep them growing. In February pot the plants, using 4 or 5-inch pots, according to the strength of the several plants. If care has been taken to pinch those requiring to be pinched during winter, the plants when potted will be stout and bushy, and will require much the same treatment as already advised for the earliest-struck batch. They may either be flowered as small plants in early summer, or if potted into 7-inch pots will make strong fresh plants for flowering later on. The same plants do very well a second year in the same pots, but though perhaps more floriferous the trusses are not so fine as on young plants. As to sorts, all those we have had during the past year or two have been good. Single varieties are more easily managed, and are more floriferous, but I do not like them so much as the double varieties either for beauty or usefulness. In addition to their adaptability as pot plants, some of them are very suitable for growing in baskets or for drooping over the edge of stages. The stronger-growing kinds run very rapidly up pillars when planted out, and are also of value for covering wall. We have hedged them for several seasons, and though in our locality they cannot be said to have proved of great value, still, in singles Progress has been passable, and of the doubles the old Anna Pfitzer is perhaps the best. Sylphide and Madame Crousse also do fairly well.—B.

#### SAVING LABOUR AND PLUNGING PLANTS.

In establishments where plants are grown by thousands for decoration and forcing there are necessarily large numbers that are turned out of the houses when the weather is favourable in spring and early summer. These are generally stood upon walks, or in any position where the supply of water is convenient. To have these plants again in good condition for autumn and winter they need considerably more labour in keeping them supplied with water than in all other cultural requirements together. The labour required for this purpose in some establishments is enormous, and during tropical weather very little other work could be done. This is a serious matter, not so much because other work lags behind, but to pour water into the pots two, three, or four times a day is injurious.

Those who have made any study of the conditions under which plants thrive best as regards moisture at their roots know that to have them wet and dry several times during the day is not conducive to health or vigorous growth. It would be difficult to name any treatment more likely to bring plants to a complete standstill, and thus predispose them to the attacks of insects and disease. Plants that have to be so frequently watered soon display to the intelligent observer by the yellow sickly appearance of their foliage that something is wrong. They need not be turned out and examined, for the roots or feeders have been injured, and the supply of water and food necessary to maintain the foliage healthy and the plants vigorous has been cut off. Exactly the same results follow when plants have been given insufficient to soak the whole of the soil; the lower leaves flag, turn yellow, and eventually fall if not removed. It may be asked, Why do not the plants die when watered on such principles? Simply because the whole of the roots are not injured at the same time. Those nearest the top of the ball that have received the water are ample to keep the uppermost portion of the plant alive, lingering between life and death.

Plants succeed much better when the soil about their roots can be kept moist without applying water too frequently. It is an impossibility to keep the soil always in an intermediate state of moisture, therefore it remains for us to endeavour to keep the soil moist as long as possible after water has been applied, so that as long a space of time may elapse before another application is needed. This can be accomplished by preventing evaporation, and the best means at the disposal of cultivators is to plunge the pots and supply the moisture evaporated by syringing or otherwise. Plunging plants in pots has been condemned as an unsafe system of cultivation, principally because the soil is liable to become saturated and sour from overwatering. I fail to see that a useful and beneficial system should be condemned because those entrusted with the watering carry out the operation carelessly. Young men that intend to grow plants successfully must learn to water plants as well when they are plunged as when they are not. Plants that are plunged to the rim in soil, ashes, or other material dry less quickly than when stood upon the surface, and even if they do become dry the roots are

less liable to suffer than those subject to the sun and drying influence of the atmosphere. Many plants, such as Roses, Prunuses, Lilacs, Solanums, Callas, Bouvardias, and many others will bear not only being plunged to the rim of their pots, but the pots and surface of the soil may be covered. This is a much better system than plunging merely to the rim, for it prevents evaporation, and the soil will remain moist for a long time. If the plants have just been watered, or the soil is moist when they are plunged, they will need no water for a long time provided they are well syringed daily, and the surface of the plunging material kept moist. In addition to this system saving days, and in the end weeks of labour, the plants will remain healthy. No system that we have yet practised has kept the soil about the roots in that uniform condition so long as plunging the pots entirely, and not the slightest injury to the plants will result. It may be argued that Solanums, Callas, Salvias, Bouvardias, and such plants would receive a serious check when they had to be removed if they rooted through the pots into the plunging material. Cultivators need not be alarmed at a few roots getting out of the pots, for if the plants are carefully treated no harm will follow. Plants such as indicated can be lifted from the open ground and repotted without any apparent injury, for the roots are not mutilated to such an extent by removing the few outside as what they are by the lifting system. After they are lifted out if soaked with water, placed behind a north wall, and kept well syringed for ten days or a fortnight, they will stand in any position afterwards.

The system of burying the pots should commend itself to all who wish to save labour in watering, have healthy instead of sickly plants, and reduce to a minimum the care and responsibility of production.—WM. BARDNEY.

#### HARDY FRUIT GARDEN.

NOTWITHSTANDING a cold late spring and frosts night after night in May, and even in the present month, the fruit crop both of Peaches and Nectarines is a full one. Never did we see the fruit set and swell more freely, and it has required some resolution to thin it sufficiently to insure fine fruit. The foliage is singularly free from blister, only two or three trees being slightly affected by it, and we have now the pleasant task of the selection of fruiting wood for another season from a clean sturdy unchecked spring growth, and the certainty of fully developed well-ripened wood in autumn. Again we say avoid overcropping, avoid crowded wood growth, retain only enough wood to fill wall space or to bear fruit. Not one shoot more should we suffer to remain upon the trees than we require for either purpose. After the disbudding has been done do not indulge in rash pinching of the growth of young trees, but rather do all you can to encourage free unchecked growth. When the young wood of old trees has a tendency to put forth sub-laterals much good may be done by pinching the sub-laterals and cutting off half of each leaf growing near the base of such untimely growth. If this shortening of the foliage can be done when we notice the first symptoms of sub-lateral growth we should by checking the flow of sap do much to prevent it. Sound judgment, common sense, and we may add prescience of development, are certainly highly important qualifications in those who undertake the culture of Peaches and Nectarines. We should know what is possible in the development of wood growth, foliage, blossom, and fruit. A glance at the condition of a tree should enable us to see whether ordinary, moderate, or hard pruning is necessary to promote that end and aim of good culture, robust wood growth and fine fruit. It is now that we are best able to decide how each tree should be pruned next winter, and there should be no hesitation in marking all trees of weak growth for a severe course of treatment then. Experience has shown that a Peach tree is naturally as elastic as a Grape Vine, its wonderful recuperative power enabling us to restore the pristine vigour of trees apparently worn out by hard cropping or other improper treatment.

See to the timely training of the new growth of all young fruit trees, taking care to fasten the shoots loosely, so as to allow space for swelling growth. Destroy caterpillars, of which many may be found feeding upon the foliage of dwarf Apple trees at this season of the year. Aphides attacking the shoots of Cherry trees should be destroyed by sponging or dipping the shoots in a strong infusion of tobacco, the trees being afterwards syringed with clean water. Continue the use of sewage freely to assist the swelling fruit. In doing this do not be satisfied with mere surface wetting, but take care that enough is given each time to reach the whole of the roots.

#### FRUIT FORCING.

VINES.—*Late Houses*.—*Thinning*.—However pressing other matters, there must not be any delay in thinning late Grapes, and in order to

secure large and highly finished berries, thin them well, especially in the interior of the bunches, leaving the larger-berried varieties, such as Gros Colman, Gros Guillaume, &c., about an inch apart, the oval-berried varieties not requiring so much room as the round ones, but all should be so thinned that they will have space for swelling fully without wedging, and yet be so close that when dished they will retain their form. Loose bunches that show the footstalks, however fine the berries, are not so pleasing in appearance as more compact bunches. Black Morocco and other shy setters are often thin of berries through the number of stoneless ones that must be removed, to guard against which no pains should be spared in getting the wood ripe, and in fertilising the bunches when in flower with pollen from Black Hamburg. Not only is it necessary to thin the berries, but the bunches must be reduced to that number which their size and condition of the Vines warrant as likely to finish satisfactorily. If an error is made let it be on the safe side, as Vines that are overburdened never finish their fruit well, and it is inferior in keeping qualities.

*Watering*.—The inside borders should be well supplied with tepid water, following in the case of Vines that are carrying full crops and in good but not too vigorous health with thicker liquid manure, also in a tepid state, mulching with short material, which kept moist will give out ammonia and attract the roots to the surface. To allow the border to get dry at the surface causes the roots to strike down in quest of moisture, the crops finish badly, the wood does not ripen well, and the consequence is the Vines start badly; the bunches instead of elongating, curl, twist, and wither, or if they escape that, the bunches are often spoiled through shanking. Neglect in watering borders that are well drained, as all Vine borders should be, and mulching, especially where the Vines are carrying a heavy crop, is not only disastrous to the present crop, through inducing attacks of red spider and premature ripening of the foliage, but injuriously affects next year's crop of fruit. Outside borders will only need mulching, as the recent rains have moistened them well, but if dry, a soaking of tepid liquid should be given whenever necessary.

*Firing and Ventilating*.—Cold nights render fires still necessary, it being a great mistake to let the fires out now and have to fire hard later on when the sun has less power to ripen the fruit. All late Grapes thrive best in a high temperature with abundant food both at the roots and in the atmosphere. Fires should be employed to maintain a night temperature of 65° and 70° to 75° by day in dull weather. Admit a little air early, a little at the top of the house constantly, increasing the ventilation with the temperature, allowing an advance to 85° or 90°, at which keep them through the day from sun heat, reducing the ventilation with the declining sun. Close at 85°, damping the paths, &c., well then, and again before nightfall. It is well to close for a short time, and afterwards admit a little air, which will prevent a vitiated atmosphere and allow the foliage drying in the morning by the time the sun acts powerfully. Late Grapes are generally backward this season, hence the desirability of making the most of sun heat and aiding with artificial. Avoid cold draughts or sudden depressions of temperature, as they cause rust.

*Regulating the Growths*.—Allow all the foliage that can be exposed to light, but when the space is fairly covered with leaves keep the shoots closely pinched. An excess of foliage is not good, though it is often encouraged with a view to root-action, but it is elaborated sap that builds up the structure of the Vine, the crop of the current year, and the wood and buds that give the fruit of the next. Foliage should be rather thinner in the case of white Grapes than in black, this more particularly applying to Muscats. Avoid large reductions of foliage at a time; it only tends to cause shanking through the check given the roots. Keep the growths tied down from the glass, and so prevent scorching. Vines extending should be allowed to make as much lateral growth as practicable, always bearing in mind the wood on which fruit is to be borne next season must have full exposure for its foliage, as the principal leaves that elaborate the sap and transmit the assimilated matter that forms the buds at their base. The laterals from these having been stopped at the first joint, they may be allowed to ramble afterwards, subject to their not interfering with the access of light and air to the main leaves.

PEACHES AND NECTARINES.—*Early House*.—The fruit will shortly be all gathered. Admit all the air possible day and night. If the roof lights are moveable take them off after the trees have had full ventilation for a fortnight, and keep the foliage free from insects by forcible syringings. Softsoap, 3 ozs. to the gallon of rain water, will destroy red spider, and if scale be present use petroleum, a wineglassful to 4 gallons of water, to which has been added half ounce of soda, and 4 ozs. soft-soap thoroughly dissolved, keeping the petroleum well mixed with the water during its application. Keep the borders well watered, affording liquid manure to weakly trees, it helps them to plump the buds; and mulch with short manure. Cut away the wood having borne fruit to the shoot at the base intended to fruit in its stead next year, unless such shoot is required for extension. If there be a superfluity of shoots remove them now, they only keep light and air from the principal foliage, and hinder cleansing operations. Keep laterals and any gross shoots closely stopped.

*Houses of Ripening Fruit*.—Trees with the fruit ripening must not be syringed, but a moderate moisture should be maintained until the fruit is ripe, and even when ripe an arid atmosphere should be avoided, as it is highly prejudicial to the foliage. Water must also be given the roots liberally. Admit air abundantly. In gathering Peaches great care is necessary, as the least pressure makes a mark and spoils their appearance. A piece of wadding should be held in the hand, and the fruit removed by gentle pressure, and then laid gently in a padded basket or tray. A cool and airy fruit-room is best place to keep Peaches and Nectarines after they are gathered.

*Trees Swelling their Crops*.—Stoning being over, the trees will stand

a strong heat without fear of the fruit falling. Afford tepid liquid manure to the roots of trees carrying full crops, and otherwise not too vigorous, but be careful in giving liquid manure to very vigorous trees, as it tends to its increase, and may so exert influence as to interfere with setting and stoning in the succeeding year. Still liberal treatment is necessary, good surface mulchings and copious waterings every week or ten days in well-drained borders. Syringe twice a day to keep down red spider. Ventilate early, keep through the day at 70° to 75° artificially, and 80° to 85° with sun heat, and close sufficiently early to increase to 90°. This with plenty of moisture in the house will insure large fruit, and if care be taken to give ventilation before nightfall no disaster will arise if it be increased sufficiently early in the morning, but if a close and high temperature be maintained the fruit, though large, will lack flavour, and not infrequently has a musty taste, particularly if the water hangs for any length of time on the fruit after syringing. Keep the fruit with its apex to the light, laths across the trellis will admit of this being done perfectly, and clear away the leaves from the fruit, but do not cut them away unless it cannot be helped. When approaching ripening admit air freely, and 60° to 65° will be a sufficiently high temperature at night or artificially in the daytime, unless the ripening is wanted accelerated, when it should range 70° to 75°, and 10° rise from sun.

**Fruit Stoning.**—Maintain a steady temperature of 60° to 65° at night, and 5° to 10° rise by day, and the usual advance of 5° to 10° or 15° at closing time from sun heat. Avoid a close atmosphere, and maintain as uniform a condition of temperature and moisture as practicable. Sudden fluctuations of temperature and cold draughts are very pernicious; equally disastrous is insufficient water at the roots. Allow a moderate extension of growth during this trying time, and do not permit a great percentage of fruit to go to the stoning that must be removed afterwards, but remove in good time. A superfluity of fruit at stoning jeopardises the crop, and even if the trees succeed in stoning it rarely finishes well, but falls off small and flavourless, and a failure another season may be anticipated. Stop gross growths or remove them altogether, so as to keep up an equal diffusion of growth throughout each individual tree.

**Late Houses.**—Train the growths thinly, reserving a shoot at the base of the current fruiting wood, and stop the growths on a level with or above the fruit at two or three leaves, and succeeding growth at a joint or two of growth. Side growths on extensions not required for furnishing the trees may be stopped at an inch or so of growth to form spurs, and by adding to the foliage will much encourage root-action and benefit the fruit; besides, these spurs usually set and swell fruit when the stronger growths on young trees do not. Thin the fruits to a few more than will be required for the crop, retaining the largest and best placed, and do not allow more than a fruit to each foot of trellis covered by the trees, but a few more may be left to meet casualties in stoning. Syringe twice a day except on dull days. During the prevalence of dull weather an occasional syringing will be all that is necessary, as it does not answer to keep moisture hanging on the foliage. Indeed, the leaves should always be dry, or nearly so, before dark. Water inside borders fortnightly, and afford liquid manure to weakly trees. Mulch the border with short manure, and keep it moist—a mulching on dry ground is no use whatever.

**CUCUMBERS.**—When the night temperature can be kept from falling below 65° fire heat may be dispensed with, much being effected by husbanding the sun heat and early closing. Continue to look over the plants weekly, well thinning the old growths, training young in their place, avoiding overcrowding and overcropping as great evils certain to result in disaster. Afford liquid manure copiously twice a week, and surface dressings of lumpy loam, supplying ammonia by sprinkling the bed occasionally with horse droppings, but be careful not to overdo it, or the foliage will suffer irreparable injury. Syringe on clear days in the afternoon only, but keep a good moisture in the house all day long by damping available surfaces as they become dry. Morning syringing is often the cause of much injury to the foliage. Shade only to prevent the foliage flagging, and be careful to apply it promptly on bright weather succeeding a dull period. Ventilate early, but avoid cold draughts, and never admit air in such volume as to lower the temperature. Keep through the day at 75° to 90°, according as the force of the solar heat dictates; in bright weather between 80° and 90° should prevail in the house from 8 A.M. to 6 P.M. Close early so as to increase to 90° or 95°, and admit a little air before nightfall as a safeguard against condensed moisture, increasing it from 7 to 8 o'clock on fine mornings.

**Pits and Frames.**—Night coverings will hardly now be necessary, but if put on it should not be done until the sun is off the frames, and it should be withdrawn early in the morning. Ventilate at 75°, and increase with the sun's elevation, keeping through the day at 80° to 90°, closing at 3 to 4 P.M., then syringe, and after being closed for an hour or two admit a little air at the back of the lights to allow of any pent-up moisture escaping. Supply liquid manure occasionally, but keep it from the foliage and fruit, and let it be weak and tepid. Remove bad leaves as well as exhausted growths, thinning the shoots once a week, stopping the growths one or two joints beyond the fruit, and when the plants are enfeebled by bearing top-dress with lumpy loam, and layer some of the younger growths at a joint from which fresh roots will be emitted and strengthen the succeeding growths.

#### PLANT HOUSES.

**French and Fancy Pelargoniums.**—For early flowering another season cuttings may be rooted without further delay. For decoration in 5 and 6-inch pots plants raised from cuttings annually are decidedly the best. Strong vigorous shoots should be selected for this purpose, and not

mere flower stems after the shoots have become woody and the plants exhausted by flowering. There are generally one or more shoots on each plant that can be taken for this purpose, and the operation can be continued as the plants come into flower until the requisite quantity have been raised. Insert the cuttings singly in sandy soil in 2-inch pots, and if placed on a shelf where the temperature ranges about 60° they will soon form roots. While in this position they should be kept moderately moist and shaded from strong sun. Directly they are rooted they may be gradually hardened and grown under cool airy treatment. The point of the young plant should be removed to induce it to branch, when they may be removed into larger pots. The majority of the varieties will only need pinching twice to form bushy specimens. The earliest plants should not be pinched after the beginning of September. Old plants that it may be necessary to retain for another year should, when they cease flowering, be exposed to full sun outside and kept rather dry until the wood is hard and ripe. During heavy rains the plants are better turned on their sides.

**Zonal Varieties.**—The majority of the plants required for winter flowering may be placed in their largest pots. Frame room will now be more abundant, and these plants must be established in their pots, and at the same time gradually hardened in such positions and then turned outside. The sooner they can be stood outside the better, so that firm sturdy growth will be made, for upon this depends whether the plants flower satisfactorily or the reverse during winter. If plants are required in 3 or 4-inch pots for decoration root cuttings without delay. Many free-flowering double and semi-double varieties are serviceable in these sizes during the winter. Although they do not flower so freely as many singles, they last much longer in good condition in rooms, and when they have done duty there they can be conveyed to the rubbish heap. Root them in thumb pots, then place them in the sizes named and stand them outside.

**Ivy-leaf Varieties.**—The improvement that has been effected with these is wonderful, and many produce their lovely flowers freely, possessing much better habits than the old forms. Where cut flowers are required during summer and winter a number of these plants should be grown. Young stock to be in good condition for autumn and early winter flowering should be ready for transferring from 3-inch pots to others 2 or 3 inches larger. The soil may be pressed firmly into the pots to prevent a quick soft growth, consisting of fibry loam, one-seventh of manure and sand. They should be well established in their pots in a cold frame, and then stood upon a bed of ashes outside, where they will be fully exposed to the sun. These plants flower freely if they possess short-jointed, firm, well ripened wood when housed in autumn. The shoots may be pinched from time to time to induce them to become bushy. Few plants pay better for planting out than these under glass in some cool airy sunny position.

**Calceolarias.**—Sow seed where plants are required in bloom as early in the season as possible. A pan or pot may be filled with light sandy soil, and the surface made even and fine, on which sow the seed. It should not be covered, but watered with a fine-rose can, and then covered with a square of glass with damp moss laid on the surface, and the pot or pan stood in a cold frame with a northern aspect until germination has taken place. Light and air must then be gradually admitted to the young plants until they will bear full exposure in the frame.

**Cinerarias.**—Place the earliest plants without delay into 5-inch pots, and grow them from this time under cool airy treatment. Younger stock may be placed into 3-inch pots from pans into which they were transplanted from the seed pot. Those sown some time ago will be ready for pricking out singly. Another pan of seed may be sown. These plants, in whatever stage they may be in, are much better grown cool than in a heated structure. If possible they can be grown in frames where they will receive abundance of light, but be shaded from the sun without the aid of artificial means.

**Celosias.**—To obtain plants for winter decoration seed should be sown at once in gentle heat. Cover the seed lightly, and shade the pan from the sun until germination takes place. Directly the seedlings are large enough they may be pricked singly into small pots, which is preferable to placing them in pans or boxes, because from these they cannot be potted without receiving a check, and it is important that they be grown steadily without a check if fine large well developed plumes are anticipated.

#### ROSE AND HORTICULTURAL SHOW FIXTURES, JUNE AND JULY, 1886.

THE following are the dates of the principal Shows to be held during June and July this year. The great event of the season will be the provincial Show of the Royal Horticultural Society at Liverpool at the end of June.

Manchester National Horticultural Exhibition, Old Trafford, June 11th to 18th.

Brentwood, June 17th and 18th.

Royal Horticultural Society Committee meetings and Pelargonium Show, June 22nd.

York Floral Fête, June 23rd to 25th.

Royal Horticultural Society Provincial Show at Liverpool, June 29th to July 5th.

Bagshot and Windlesham Rose Society, at Bagshot, Tuesday, June 29th.

Canterbury and Kent Rose Society, at Canterbury, Tuesday, June 29th.

Diss Horticultural Society's Rose Show, June 30th.

Royal Botanic Society's Evening Fête, June 30th.

Farningham Rose and Horticultural Society, at Farningham, Wednesday, June 30th.

Croydon Horticultural Society, at Croydon, Wednesday, June 30th.

Reigate Rose Association, at Reigate, Thursday, July 1st.

Tunbridge Wells Horticultural Society, at Tunbridge Wells, Friday, July 2nd.

Brockham Rose Association, at Dorking, Saturday, July 3rd.

Eltham Rose and Horticultural Society, at Eltham, Saturday, July 3rd.

Crystal Palace Rose Show, Saturday, July 3rd.

National Rose Society, at South Kensington, Tuesday, July 6th.

Cardiff Rose Society, at Cardiff, Wednesday, July 7th.

Sutton Amateur Rose Society, at Sutton, Wednesday, July 7th.

Oxford Rose Show, Wednesday, July 7th.

Ealing, Acton, and Hanwell Horticultural Society, at Ealing, Wednesday, July 7th.

Bath Floral Fête and Band Committee, at Bath, Thursday, July 8th.

Ipswich and East of England Horticultural Society, at Ipswich, Thursday, July 8th.

Hitchin Rose Society, at Hitchin, Thursday, July 8th.

Hereford and West of England Rose Society, at Hereford, Friday, July 9th.

Maidstone Rose Club, at Maidstone, Friday, July 9th.

Wirral Rose Society, at Birkenhead, Saturday, July 10th.

Leek Floral and Horticultural Society, at Rudyard, July 31st and August 2nd.

## THE BEE-KEEPER.

### THE WAY TO SUCCESS.

THE great charm in bee-keeping is that each one has room for the exercise of individual ingenuity. Nature has indeed laid out a broad safe road, which will be found by those who travel on it to lead to the end for which Nature laid it; but the majority of bee-keepers are not content to go a long way round when they are able to attain their object by a shorter, and, in the case of an experienced man, a no less safe and easy road. Occasionally these bypaths do not fulfil the expectations of those who travel on them; they lead to difficulty and eventually to ruin, instead of to success and profit. Most intelligent bee-keepers have some favourite bypath; one points to this ideal way to success, another to that; each one thinks for a time his own the best. Nature bids bees to swarm, man saves them this trouble or pleasure, and the time wasted in the varied manœuvres precedent to the issue of a swarm lasts occasionally if the weather is unsuitable for many weeks; or possibly in his spirit of self-aggrandisement the bee-master, by giving young queens and continually providing room in advance of the wants of the stock, not only takes away the desire—ever present when an aged queen is ruler of the hive—to supplant the disgraced queen, but prevents such desire from arising. Yes, in bees old age and crippled limbs are a disgrace; they have no hospitals, no almshouses, no poor law union; they live, they work, and when they can work no longer they simply die. A few words on this subject may be useful at the commencement of the busy time of the year to those engaged in bee-keeping.

It is very generally imagined that anyone who desires to do so may become a successful bee-keeper. This is only partially true, for if a hasty thought is given to the success or failure of the bee-keepers of a certain neighbourhood the failures will in most districts predominate. A fair minority do gain good profits, while the majority scarcely manage one year with another to pay their expenses. Bee-keeping is a pleasurable industry, but it cannot be taken up to-day, neglected to-morrow, and profit gained the day following. Thorough care and practical experience, combined with a thorough knowledge of the requirements and habits of bees, are all necessary qualities to make a successful bee-keeper, and, in addition, the knowledge of when to do a thing and how to do it. If a road is to be laid surely the foundation, if not already existing, must be made firm and solid, and then the surface welded carefully together; but some bee-keepers first lay the surface, and then, when the crust gives way, try to prop it up with any materials which can be

pressed into use in cases of emergency. If bee keepers will bear this in mind their troubles will be materially diminished.

The knowledge when a thing ought to be done, and what ought to be done in case of emergency, is after all the great obstacle to success: everything else can be acquired more easily than this, the most necessary knowledge of all. Time, experience, and eyes that see, and a mind that understands, must all be pressed into service by the man who desires to attain these most useful qualities. But how to do a thing is not nearly so difficult a matter. It is from a beginner's point of view, I know, much easier to read how to perform a certain manipulation than to put the teaching into practice; but a great incentive to most men is that if they fail in doing what others perform with ease, they are proved in that particular instance to be inferior to their fellow men. What man has done men can do! In bee-keeping there is no manipulating necessary for profitable management which cannot be performed by every individual person who determines to succeed. Nothing succeeds like success, and nothing ensures success so much as determination to succeed. Each one may take courage in that he can do anything connected with bee-keeping in the way of manipulation. This very facility to manipulate is the bane of modern bee-keeping. The time occupied is far greater than is warranted by any additional profit gained; the bees are continually upset and disturbed, and the apiarian does wonderful things with his bees, but when the time comes for balancing the year's accounts, "all is vanity," and bee-keeping unprofitable.

To such, indeed, the bees yield but a poor result. There has been "a great cry and little wool," as they say at the shearing of hogs. Now to those who have laid any of these short cuts to success to which I have before referred, I will only say, Are the foundations properly laid and strong enough to support the surface? because, if not, by all means strengthen them, and if this is impossible then return to Nature's highway, and travel upon it for another year, reading the works of great bee-keepers, and gaining a knowledge of how to place the lower layer before spreading on the higher. Learn how to do the essential acts in an apiary, and trust to common sense and natural insight, cultivated by judicious reading and conversation with others, to point out the right time to do the right thing, and do it at once without delay. Let there be no procrastination, no waste of energy, no unnecessary manipulation, no increased expenditure unless increased returns can reasonably be expected. Let it be continually borne in mind that the price of honey is low, and likely to become still lower; and cheap production can alone enable bee-keeping to maintain its position as a profitable industry. The less time and money required to produce a pound of honey the more easily can a reduced price be met. Time and money are one and the same thing. Until a sufficient knowledge has been gained, follow the teaching of others, and when such a knowledge has been acquired let individual judgment have full play, and good results will follow.

Bee-keepers are but mortals, and as a child must walk at first with the aid of a mother's arm, so the bee-keeper in his early days must lean on others who stretch out a friendly helping hand, but when manhood comes and childhood days have gone for ever, each one should step out fearlessly, trusting in his own strength. Those who cannot do so are poor cripples, sad to contemplate, pitiable to behold. I have written these lines as a hint to some who may be led by advanced bee-keepers to stop and consider their position. I ask them only two questions. Does the present state of the honey market warrant increased expenditure unless it can be shown that such increase gives a sure return? Do those who spend most money in appliances and time in manipulation make the greatest profit?—FELIX.

### DOINGS OF THE PAST WEEK.

THE continuation of the cold until June induced me to commence feeding some of my hives as a preventive of going back by drawing

brood. To the most needful I gave half a pound of sugar to each. On the 2nd of June the weather changed for the better, and I withheld giving more. On the 7th June the temperature for the first time this season stood at 73° in the shade. The bees were carrying in much pollen and honey, and had increased in weight greatly. A number of the hives appeared as if preparing to swarm. Being too early to put on supers, I gave them full doorway and ventilated a little. The bees all retiring from the front went to work with extra vigour. To put on supers yet would be unsatisfactory, as the yield of honey at this season being from different sources will not make a good sample, and whether or not I must have the hives filled with stores or nearly so for next season before I attempt supering. The strength of my hives will do this in three or four days, then all will be surplus after. Swarming is now general, and if the season is late will suit the bees all the better. A month's fine weather in the end of June and beginning of July will do much good, and will be very acceptable. Until the fine weather and flowers come together, neither neglect feeding nor put on supers. If more room is needed, add to the body of the hive. Be careful not to neglect the feeding of swarms, and preserve as many young queens in nuclei as are likely to be required. Have everything in readiness, and be prepared for any or every emergency that may arise.—LANARKSHIRE BEE-KEEPER.

#### EASTERN DISTRICT OF STIRLINGSHIRE BEE-KEEPERS' ASSOCIATION.

A MEETING of this Association was held at Carron in the Old Inn, Mr. Baird's, on the evening of Friday, the 4th June. About twenty members attended. Wm. Sword, Esq., Bonney View, Falkirk, presided. The business of the meeting was the arranging for the coming Show to be held in Falkirk end of August, and to co-operate with that Society in holding their annual shows. The circulars calling the meeting announced that "A Lanarkshire Bee-keeper" would address the meeting. Mr. Sword introduced him, and said in addition to what Mr. Thomson would explain in his address he would also answer any questions the members desired to put. The address embraced the natural history of the honey bee, and the system most likely to secure the largest amount of honey in this changeable climate, together with the best mode of wintering bees, which was the key to success. The business and the lecture occupied two hours and a half. Thereafter queries were put. It so happened they were identical to those answered in this Journal, which were handed round to the querists, Mr. Thomson meanwhile urging all present to become not only readers, but writers, to the *Journal of Horticulture*, the pioneer in bee-keeping, and the only really practical journal on gardening, farming, and bee husbandry that was published. The members were favourable to this proposal. A good deal of merriment was created when Mr. Thomson said we would all have to look ahead if we wished to preserve our laurels, as they were being quickly appropriated by young bee-keepers of from six to ten years' standing, who seemed to have the knack of inventing things that were in use for a quarter of a century, of which happily the *Journal of Horticulture* carried proof in its earlier numbers. The *British Bee-Keepers' Record*, too, lay on the table, in which Raitt's honey press was announced as having the Lanarkshire powerful screw attached, which was a great improvement over the pump handle; but why it should be called the Raitt honey press was a mystery, and the same applied to Raitt's fume chamber for carbolic acid. Amid much laughter the meeting was brought to a close, when a vote of thanks to the chairman and Mr. Thomson was accorded. At the close several very pretty hives were shown, being the work of amateurs, but in this case, as in many others, beauty and utility were not combined.

#### NUTT'S HIVE — BEES ROBBING.

I HAVE a Nutt's hive divided into three compartments so that I can keep three distinct stocks. I have a stock in the middle compartment, and an end one, but the bees in the other compartment died last winter of dysentery before I bought the hive. On Sunday, June 16th, about 2 P.M., there was a great commotion at the end hive; the bees could not get in and out fast enough—in fact, a neighbour's bees were robbing them. Is it not rather an unusual thing for bees to rob in June? In the evening I turned the hive up and examined it. They had evidently lost the queen some time, as there was a queen cell sealed up, and they were far from being in a condition to swarm, as they had been very weak and were still far from strong. I cut out the queen cell, and on examining it found two fully developed workers in it (dead). It was a young queen, because they swarmed last year. While the robbing was going on, the bees in the middle hive were very excited, they clung on the alighting board and all over the entrance in great numbers all the afternoon, but they went to work again all right on the next day.—H. T. S., *Lincoln*.

[A single compartment of a Nutt's hive is far too small for any stock of bees. The inventor intended the three boxes to form one whole: the two end ones to be used for depriving, the centre for the brood chamber. Robbing in June or at any other time is not a rare occurrence if there is little honey to be had in the fields. A weak or queenless stock is sure to be first attacked, but every hive will be attacked in turn if care is not taken to prevent the success of the thieves. An ordinary queen cell could hardly contain "two fully developed workers." If at the time the queen was lost there were no eggs or young larvae in the hive the bees would be unable to raise a successor, but if the queen had laid up to within a few days of the time of her loss a successor could easily have been raised. Steps must at once be taken to either requeen the bees or to unite them to

another stock. Probably the latter will be the best plan, but without knowing more about the state of the bees and comb it is not possible to give any decided advice.—FELIX.]

#### TRADE CATALOGUES RECEIVED.

W. Lovel & Son, Weaverthorpe, Yorkshire.—*Select List of Strawberry Plants.*

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

TO CORRESPONDENTS.—We desire to assure those of our correspondents whose letters and communications are not promptly inserted that they are not the less appreciated on that account. Our pages are practically filled several days prior to publication, and letters arriving on Wednesday morning, except by special arrangement, are invariably too late for insertion. The delay in the publication of some of these is not of material importance, but reports of meetings and shows held a week previously lose much or all of their value if not received in time to appear in the current issue.

Books (*Great Barton*).—We know of no book of medium size that gives better instruction on all-round gardening than the "Cottage Gardeners' Dictionary." It contains information on nearly everything, with full details for growing the more important plants, as well as fruit and vegetable crops. It can be had from this office, price 7s. 6d., post free 8s. 2d. (*A. L. D.*).—Barron's "Vine Culture" gives all the necessary information for growing good Grapes. The leading varieties are also well illustrated in the work. Price, from this office, 10s. 6d. (*J. Marks*).—"Mushrooms for the Million" is in the press and will be ready very shortly.

Tubes for Exhibiting Roses (*Kittie*).—The tube to which you refer is probably Foster's Rose Holder, an illustrated advertisement of which appeared in this Journal a fortnight since. Those tubes are largely used and, as the advertisement states, are made and sold by Mr. Foster of Ashford, Kent.

Marguerites Malformed (*M. J. T.*).—The most common cause of the malformation of flowers is the attacks of insects, not necessarily at the time of expansion, but as soon as the buds form, and often before they are clearly visible. The slightest injury by puncture at that stage naturally develops as the buds swell and the petals and florets expand. We have known these and many other flowers so distorted as to be quite spoiled by insects puncturing the buds some weeks or months previously. We are answering your letter on the assumption that your plants are healthy and have the requisite support for perfecting their flowers; if that is not afforded failure more or less marked must be the inevitable result.

Bottle-brush Tree, *Metrosideros floribunda* (*Stirling*).—This plant requires a compost of peat and sand with good drainage, and the temperature of a greenhouse or conservatory. Water must be carefully supplied at all times, neither allowing the soil to become too wet or dry. It may be propagated by cuttings of the half-ripened wood at the end of summer, inserting them in sand and placing the pots in a cool frame for a week or two, when they can be removed to a house or frame with a temperature of about 60°. The cuttings are slow in forming roots, and until that is effected they must be very carefully supplied with moisture.

Cropping Vines (*E. M.*).—It is quite impossible for anyone to say how many bunches you should leave on your Vines without knowing whether they are strong or weak, and whether the bunches are large or small. A vigorous Vine well supported will furnish 2 lbs. of Grapes to each lineal foot of rod better than a weak Vine will ripen half that weight. It is a great mistake to overcrop Vines, and it also indicates a lack of judgment to have to relieve overladen Vines by cutting off bunches after time has been spent in thinning them, as in such a case the time has not only been wasted but the Vines needlessly exhausted. Superfluous bunches should be removed as soon as the Grapes set, if not sooner; and if there is a doubt as to how many to remove give the benefit of it in favour of light cropping. A crop of Grapes that looks "light" now will have a very different appearance in two months' time. If lateral growth practically ceases before the fruit commences colouring, that will be proof of the crop being too heavy for the Vines.

**Early Beatrice Peach (J. M.).**—The fruits not having been packed securely arrived in the form of jam, caused by shaking to and fro in the tin box. This also nearly converted the paper on which you had written to its original pulp, and we can only decipher a portion of your letter. Your Peach is probably correctly named. It is one of the earliest in cultivation, and the following the description:—Fruit medium sized, 2½ inches in diameter; round, a little pointed at the apex, and marked on one side with a distinct suture. Skin with a yellowish ground, but almost covered with blotches of bright red, and altogether very highly coloured. Flesh melting and juicy, richly flavoured, and adhering slightly by some of its fibres to the stone, which is white. Flowers white. Leaves with kidney-shaped glands.

**Orange Fungus on Roses (J. W., Pershore).**—We have never seen a worse attack of this fungus than on the shoot and bud you have sent. No application could effect a cure in such an extreme case, for the bud could not possibly expand and develop into a presentable flower if it had been left on the plant. A weak solution of sulphate of copper has been found of service. Dissolve 2 ozs. of blue vitriol in hot water, then mix in two or three gallons of cold water, and apply to the affected parts with a sponge. Harris's sulphide of potassium has also been found effectual by some cultivators. It can be obtained from chemists, with directions for use. Mr. Bardney, who grows Tea Roses extensively, keeps their foliage and also that of fruit trees under glass perfectly free from mildew and insects by the following plan:—About 2 lbs. of soap are placed in a saucepan with a little water, and boiled for about twenty minutes. This is mixed with five or six gallons of water and kept in a large flower-pot. Half a pint of the solution is placed in a large water-pot full of water used for syringing. Neither insects nor mildew appear able to exist on the foliage, while nothing can exceed the admirable condition of the trees and Roses. It is important that it be used regularly—that is, whenever the syringe is employed.

**Lime Rubbish for Vines (J. C., Somerset).**—It is not necessary to crush the particles to powder; if they are broken to the size of walnuts, downwards, there will be no lack of dust. The particles and dust should be mixed with the loam. If this is of a rather strong holding nature Mr. Barron recommends in his excellent book 1 cubic yard for mixing with 5 or 6 yards of loam; but the quantity to use depends entirely on the texture of the soil with which it is to be incorporated. Large particles of lime rubbish are suitable for drainage, on which the soil of Vine borders rests, a layer of turves being laid grass downwards to keep the drainage clear, due provision being also made for the free outlet of water that passes through the borders. Provided you do not lay the cross boards on the Vine border when it is very wet they will do no harm whatever, but, on the contrary, may do good in preventing the escape of moisture from the surface of the soil in summer. We have known the surface of Vine borders netted with roots under boards that had been on the soil throughout the summer, and the roots covered with rich rough soil contributed materially to the health and fruitfulness of the Vines. We are of opinion that many Vine borders are kept too loose and dry near the surface in hot weather.

**Araucaria imbricata Coning (W. Ellis).**—Many Araucarias have produced cones in this country, and seedlings have been raised at Bicton and Dropmore. The pollen-bearing and seed-producing catkins are quite dissimilar in form, and are usually borne on separate trees, but not always. On this subject we cite from Veitch's admirable work that is mentioned on another page. "The Araucarias are not absolutely dioecious, probably far from it. There is a tree of Araucaria imbricata at Bicton, in Devonshire, that has borne catkins of both kinds for several years past, and many young plants have been raised from the seeds of its fertile cones. A fine tree at South Lytchelt, in Dorsetshire, has shown the same peculiarity. As the numerous healthy trees now growing all over Great Britain become cone-bearing, the monœcious principle may probably be found among them to an extent not hitherto suspected. The difference in the sex of the trees was generally thought to give rise to the difference in aspect and habit that occurs so frequently among plants of the same species. The Araucarias, like other Coniferae, are now known to be polymorphous, irrespective of sex, which is shown by the numerous varieties and sub-varieties of nearly all the kinds under cultivation, and are constantly making their appearance." We do not remember where the finest Araucaria is to be seen, but the magnificent Dropmore specimen was measured in 1881, its height being then 61 feet 6 inches, the circumference round the extremities of the branches as they rested on the ground 100 feet, the girth of the trunk, 3 feet from the ground, 7 feet 4 inches. It is a male or pollen-bearing form, and we have not seen a larger or more perfect example.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (A. R. C.).—Dendrobium Dalhousianum. (A. C., Liverpool).—The yellow flower is Lycaste aromatica, the other is Cattleya Forbesi. (J. R.).—1, Diplazium glutinosus; 2, Berberis empetrifolia.

**Supering (A Bee-keeper).**—It is not necessary to ventilate the supers, and if you make any perforations the bees will seal them with propolis. The supers will be quite warm enough in your bee house without extra protection.

#### COVENT GARDEN MARKET.—JUNE 16TH.

Our market very depressed, and all classes of goods lower.

#### THE FUTURE OF FARMING.

In the papers specially devoted to this subject we have called attention in general terms to the soil, manures, the economy of Nature, of practice, of time, to the importance of thorough work, the use of pure seeds, the improvement of grass land, to the reduction of rent, and the size of farms. Many other subjects present themselves to us as having an influence for good or evil upon the future of farming; but they may be dealt with more usefully in full detail, each being taken alone, and therefore we purpose bringing the general consideration of it to a close in this paper.

Success in the future as in the present, after all that can be said about it, depends more upon individual effort than anything else. A man may work hard to very little purpose if he lacks intelligence and skill for the guidance of his work, and one lesson of the depression not hard to learn is the plain fact that if any man can be a farmer it by no means follows that he will be a successful one. Farms to let are now plentiful enough; we have several, and in offering them to would-be tenants the conditions of hire are influenced by the condition of the land and the situation of the farm. In common fairness this should have weight both with landlord and tenant, and with due allowance for this, we fail to see why a really clever farmer should not make farming answer

now almost as well as heretofore. It is a popular idea that the price of Wheat should rule the rate of rent, but having regard to the yearly reduction of the area of land under Wheat, we regard this idea as a fallacy. The future of farming will witness one of two things: either the culture of Wheat will be so much improved that the result may continue to be taken as a safe guide, or the amount realised by the entire farm produce must be divided by the number of acres contained in it, and we submit that such a test would be the safe one for general adoption. To those persons intending to hire farms we would say, Do not be tempted by mere lowness of rent. We know farms that are now being offered at 6s. and 8s. an acre which we would not have rent free, for they have fallen upon the landlord's hands in deplorable condition. "Farmed out" is the term applied to them, and the term is well understood to imply both poverty and foulness, and also a probable want of drainage. If the drainage is said to be efficient, it often proves to be so much at fault as to cause serious injury to crops. We have recently been over several farms where some of the drains have become choked from some cause or other, with the serious result of a large patch of corn spoilt. We know an acre of Winter Oats so spoilt at the present time in a large field where the remainder of the crop is in excellent condition. The lesson gained by such a sight is invaluable; the land that is saturated with water being not soft, but hard and sour, the drained soil close by being soft, sweet, and mellow.

The stoppage of drains in arable land—especially in land that has fallen out of cultivation—is frequently caused by deep steam cultivation, and there is most risk of this when the drains are shallow. They are perhaps most frequently choked by foul ditches, which, having remained unscoured year after year, have an accumulation of weeds, mud, and leaves over the mouths of the drains, and we have had them quite filled by the roots of trees which grow along the pipes for a considerable distance. A main drain opened recently had the pipes filled with Elm roots running under a hard road some 40 feet wide. This leads us to mention the evil arising from an overgrowth of hedgerow timber on farms, which was probably an outcome of the easy-going prosperous days of farming. Upon asking why there were so many trees upon a farm which came upon our hands a few months ago we were told it was for the sake of appearance. Finding the farmhouse and buildings in a sadly dilapidated state we were by a judicious thinning of trees able to realise enough money to put the buildings into a thorough state of repair, and we venture to say that the appearance of the farm is now far more attractive to a practical man both as regards the condition of the buildings and the hedgerows also.

Farm homesteads are also worthy of much more attention than is given them upon many estates. There is no reason why the farmhouse and the approach to it should not be both neat and attractive; on the contrary, all that is possible should be done to make them so. But too frequently the position and arrangement of the outbuildings would appear to be the result of an accident rather than of careful forethought and well-matured plans. We know several homesteads where the windows of the house open upon the farmyard, yet this might easily be avoided without having the house far away from the buildings. A central position upon the farm with a good road to it, buildings easy of access, commodious, convenient, strong, and so connected that the whole of them may be used without difficulty, is what we require. Avoid extremes in such matters, and strive to attain the happy mean between inconvenient hovels and sheds and palatial buildings, involving an expenditure of two or three thousand pounds for a single homestead.

We neither hope nor desire to effect sweeping reforms in the farming of the future, but we would fain do what is possible to bring about improvements in culture of which so many farms are so much in need. The first step to so desirable an end is individual effort on the part of farmers at self-improvement. Might not Farmers' Clubs and Chambers

of Agriculture help in this matter? No doubt they do help in some degree by the reading of papers and discussions on practical subjects; well would it be if the meetings of such associations were confined almost solely to such sound work to the exclusion of political debates upon protection and kindred subjects.

#### WORK ON THE HOME FARM.

As the ewes are removed from the lambs for weaning the entire flock will be carefully examined, and crones or over-age ewes withdrawn from it at once to be fattened for market. This will be done by folding upon some such green crop as Tares, Trefoil, Clover, Lucerne, Mustard, or Grass, according to locality and convenience. We shall thus be doing good to the land and turning the old sheep to best account. Other ewes will be added to the flock for next season either by purchase of one-shear ewes or by drafting from other flocks. Annual attention to this is important now in order to insure a sound healthy breeding flock. Our ewes have been well fed since last October, and they are withdrawn from the lambs, somewhat low in flesh it is true, but otherwise in sound condition. If we would have fine lambs early in the season the ewes must have good food and careful treatment. Many ewes come from the lambs in such poor condition that it requires some months to render them fairly sleek. It is doubtless owing to this that breeding begins so late in many flocks. There are three ways of turning the lambs to account after weaning—they may be forced on by high feeding till the end of July or early in August, when they will have closely approached the weight and size of full grown sheep. They may be sold at once, or be kept for hoggets to be folded on roots next winter and sold in batches as they become ready for the butcher. There is still some hoeing of weeds in corn, for we keep at this as long as possible before turning to the roots. We like to get all such work finished before haymaking begins, as there is little time afterwards for it. The Mangolds have grown so fast that we hope to finish thinning and hoeing soon now. The fly has been busy among the young Swede plants, but with such favourable weather growth is quick, and we have now reason to hope we shall have no failure to record this summer. On the contrary, the whole of the crops upon our farms are in flourishing condition, giving fair promise of an abundant harvest. Growth was much retarded by a backward spring; but real summer weather effects a remarkable change in a short time among all crops. Grass for hay has much improved during the past week, and most of the late Grasses will be in bloom by the time this note is printed. Last summer we had two or three serious failures of Mustard seed, which, though only a catch crop, is an important one, as it is sown and ploughed in to impart fertility to poor soil. We have no such failure this year, for showers fell soon after the seed was sown, and the plants are growing freely. How much better this is than bare fallows we hope our readers now know full well.

#### OUR LETTER BOX.

Sowing Cattle Cabbage (*A. B. C. D.*).—The season being so much advanced you can only sow in July to have plants ready for sale by the end of September to plant out for a late spring crop, and sow in August to plant out about the end of October for a summer crop. It requires about 2 lbs. of seed to afford enough plants for an acre of land. To have strong plants make a fine seed bed on fertile soil—that in which your early Potatoes are growing will answer well—sow the seed thinly broadcast, rake in, and scatter a little fine soil over it to insure covering all the seed, or the birds will take much of it. The seed bed should be divided into plots, which can be watered without trampling upon them. Late Drumhead is the best sort for the July and August sowings. In addition to this, another season you may sow Early Sheepfold or Flockmaster in February and March to have plants ready for sale in June and July for an early autumn crop, and sow Early Drumhead in March and April for sale at the same time as Early Sheepfold for a late autumn and winter crop.

#### REMARKS.

6th.—Fine and bright throughout.  
 7th.—A glorious summer day.  
 8th.—A glorious summer day.  
 9th.—Fine, but rather close and oppressive.  
 10th.—Dull morning, with spots of rain; heavy rain from noon to 1 P.M.; cloudy afternoon.  
 11th.—A fine bright pleasant day; showers in evening.  
 12th.—Fine, with alternate bright sunshine and spots of rain; heavy shower about 5 P.M.  
 As a whole a week of bright pleasant weather, with cool breezes. Temperature about 4° above that of the preceding week, and almost identical with the average.  
 —G. J. SIMONS.

### PREPARING FOR THE SHOW.

**V**ERY few persons, except those who are concerned in the arrangement of horticultural exhibitions, have any idea of the enormous labour requisite to ensure success. Exhibitors have a peculiarity especially troublesome to secretaries and flower show managers—namely, delaying their entries until the latest possible time in the first place, and secondly when the exhibition day arrives they are not always so punctual as might be desired in getting their plants or other exhibits into their allotted positions. Perhaps also someone who has engaged considerable space fails to appear, and this contingency has to be met by a hurried partial re-arrangement. The positions allotted to certain exhibitors may not give satisfaction, and with scores of other vexations the manager of a horticultural show, even on a small scale, has not an enviable post. When there are all these difficulties to contend with in an ordinary gathering, it will be readily understood that they must be increased tenfold at an exhibition of such a varied character as that which is to be opened at Liverpool next Tuesday. This is evident from the fact that there are 125 classes for plants, flowers, fruit, and vegetables, in the majority of which there will be numerous entries, each requiring a certain space to be determined before the day of exhibition; and besides this there is an extensive exhibition of implements, greenhouses, and garden appliances to be provided for, a space for boiler trials, and an exhibition of horticultural literature, plans, drawings, paintings, &c., Mr. A. F. Barron has a formidable task before him; but his long experience in the work and his well-drilled assistants, who are familiar with the admirable system adopted at South Kensington, will soon reduce affairs to order. It is particularly satisfactory to learn that the Exhibition is likely to be one that will be worthy of the Society and of the great commercial city in which it is to be held. All that is wanted is a week's fine weather, and after such a long continuance of cold a favourable change has occurred.

A brief description of the general disposition of the exhibits will serve to indicate the probable character of the Show and the way it can be best seen. The Botanic Gardens and the Wavertree Park form an extensive oblong space, bounded on the north by Edge Lane, on the east by Botanic Road, and on the west and south by the Exhibition Road, which passes the entrance to "The Shipperies." This is opposite the Botanic Garden, and as there will be an entrance to the latter at the same point, no doubt many will take that direction. A path from there leads direct across the gardens to the large marquee for plants, and to that most visitors will first direct their steps. It is an enormous canvas erection 260 feet long by 130 feet wide, and the ground has been tastefully laid out in raised mounds, upon which the plants will be arranged. Along the two sides and a portion of the ends is a narrow bank with rounded projections and bays. At the south end is a large semicircular mound, one of a similar shape, but smaller in front, and flanked by two

circles. At the opposite end of the marquee is a large irregularly margined mound and three long curving beds, while in the centre is a circle surrounded by four oblong beds, which it is intended to devote to Orchids and general collections. Every approach to formality has been avoided as far as possible, and it may be expected that this marquee will alone constitute a beautiful exhibition.

A short distance from this to the left, if the marquee is quitted at the southern end, is the tent for table decorations, and further still in the same direction is a long tent for fruit and vegetables, both of which will be well represented. Then proceeding to the south we come to the space devoted to the boiler trials, which will be sure to yield something interesting. Turning to the right from that point the cut-flower tent is reached, and then the greenhouses, implements, and appliances, which occupy an adjoining space, can be inspected, for this department is one of importance to all horticulturists. The whole of these exhibits will be arranged in the Wavertree Park, but the Botanical Gardens which adjoin will be open to all visitors.

The Exhibition will be opened to Fellows of the Society one hour before the general public on Tuesday, June 29th—namely, at 12 noon—and will be opened on each of the other days at 10 A.M. On Wednesday, the 30th inst., a conference on the nomenclature of Orchids will be held, and on Saturday, July 3rd, and Monday, July 5th, a Cottagers' and Artizans' Show will take place in the grounds.

### ROSE PROSPECTS.

**WE** are now on the eve of our great annual tournaments, for Canterbury leads the movement on Tuesday, the 29th, and a natural anxiety is expressed on all sides to know what are the probabilities of the season. Shall we have good shows? Are the fixtures correct? Of course each grower estimates the season by the condition of his own garden, and according as his prospects are good or the reverse, so he pronounces on the season. Not being an exhibitor, I am not perhaps subject to these disturbing elements with which the exhibitors are exercised, and as I have many opportunities of seeing and hearing about Roses in other gardens besides my own, I am not confined in my observations to any one locality.

With regard to the character of the season I think it must be a late one, although so very much depends on the weather of the next fortnight or three weeks that it is impossible to state even this possibility. I have known such weather at the end of June that Roses have come in with a rush, and what was looked upon as sure to be a late season has turned out to be an early one. But everything is late this year, and I think Roses must share in the general condition of things. I firmly believe (although some ridicule the notion) that the Rose season is later than it used to be. The last Saturday in June was considered quite late enough at one time, but few would advocate such a late date now—probably the day fixed for the National will be about right. There is indeed a very great similarity as far as my own locality is concerned between this season and last, and I find the same reports from many other localities.

As to the condition of the Roses themselves, I find a very general complaint of blind shoots—i.e., shoots without flower buds. In many places this seems to be very serious, and is generally attributed to the frost at the end of April or beginning of May; but I hardly think this is the cause. It is more likely to be, I imagine, the long, cold, dreary weather of February and March, with low temperature coming after the winter. The plants seemed to lack constitution to battle against it. Even as it occurred with "humans," so many battled through the winter well but succumbed to that spell of dreary weather, and when they might naturally have looked for something to stimulate their vigour they found themselves laid low; so I think with the Roses, and hence

the blind shoots. Personally I have experienced it in a very slight degree—indeed, if my attention had not been directed to it I should not have noticed the fact.

So far there are very few complaints of aphids. There is a popular notion in our county that the east wind is favourable to bringing fly, &c., on Hops: and if the same were to hold good with Roses we ought to have plenty of aphides, for we have had more of the easterly winds this season than I recollect. With Hops I believe the injury arises from checking the growths, and when they can get away up the poles the fly is comparatively innocuous. But this is not the case with the Rose, for it is on the soft new growth that the aphid especially delights to feast. I daresay before long we shall hear complaints of it, but at present it has not made its appearance to any extent.

Mildew, which from the alternations of temperature we might have expected, is not as yet prevalent. Here and there I hear complaints of a few plants being touched by it, but that is all. We have not had hot weather sufficient to bring it out strongly, for it is when we get hot days and cold nights that it is most likely to prevail; but if it has not appeared, I find from a well-known writer, "D. T. F.," who hails from East Anglia, and seems to suffer from most Rose evils, that there has been a plague of what he calls red rust, but which we know better as orange fungus. It is, as he justly says, very early for it to make its appearance. Some years ago I used to be terribly troubled with this pest, but it never appeared until after the bloom was past; but I have had it set in with such violence then that at the end of July my small Rose garden was as bare of foliage as in November. I tried various plans, but nothing succeeded, and for three or four years it regularly appeared; but for some years past I have not experienced its ravages. Why I know not. My Roses are in the same place, and my treatment has not varied. The only thing that is different is that there used to be a small Hop garden at the side of my garden. This has been done away with, and whether the freer circulation of air had anything to do with it or not I cannot say, but since then I have not seen it. Of all the ills that the Rose is subject to this is the most disfiguring. Mildew is bad enough, but this is ten times worse. I pity "D. T. F." to have had it so early in the season, when the wood is tender, for it must of necessity be much more injurious than when it attacks harder wood and foliage.

Of the maggot the accounts vary. In some cases he is said to be very prevalent, and as usual very mischievous, but in the majority of those gardens of which I have heard or seen there is not more than the usual quantity, and where care is taken and hand-picking sedulously attended to it ought to occasion little damage. It so soon makes its presence manifest that a little watchfulness will prevent its doing much injury.

There is no prospect of any diminution either in the number or magnitude of the Rose Shows which are to be held this year. Some have passed away, it is true, but then others have arisen to take their places. If Newcastle-under-Lyme, Wirksworth, Leek, and others have died of inanition, Henfield, Ryde, Morston-in-the-Marsh have taken their place, and in some in a very spirited manner. Thus, one of the very best, if not the very best prize of the whole year is to be found in the schedule of the latter Society, where a prize of £10 is offered to nurserymen and amateurs for the best box in the Show irrespective of numbers. In the same way exhibitors pass away, grow tired of it, or remove their habitations to a less rosy district; but others come forward to take their place, and it is possible that we may see some new "hands" entering the lists this year. The National Rose Society has further stimulated the zeal of exhibitors by having had new dies cast for their medals, which the affiliated societies have obtained, and which will be competed for all over the kingdom.

Such are, then, our prospects; but, as I have said, the next fortnight has a great deal to answer for it. The

weather may be unpropitious and our best hopes be disappointed, or it may be fine, and then our Rose thermometer will go up, and when the exhibitions come there will be the making or marring of many a candidate for favour. Some speak as if Gloire Lyonnaise was to redeem its character, and, if not to come forth as a yellow H.P., yet to be a good exhibition Rose; then Her Majesty will have to stand the ordeal, to see whether she forfeits the high expectations that have been formed of her, and so with several others. Soon all surmises will be at an end, and let us hope that when we come to chronicle the results of the season we may be able to say that we have had a good time.—D., Deal.

### CULTIVATION OF THE STRAWBERRY.

As discussion is invited on the cultivation of Strawberries, and on varieties suitable for open air culture, I send these notes, which are founded on experience gained in gardens in several widely separated counties. As to soil, a deep calcareous loam inclining to be heavy is the most suitable, and where the land is of this description good results may be obtained without any extra care, such as is required in gardens where the soil is of a poor gravelly nature; yet good Strawberries may be grown in nearly all gardens if sufficient care be exercised in the preparation of the ground and points of culture. I have heard Mr. Douglas state that when he first went as gardener to Loxford Hall, it was pointed out to him that Strawberries and Apples were fruits that he would not be able to cultivate successfully, as the soil was not suitable, and that they never had done well, but with perseverance and high cultivation he succeeded. It was also an admitted fact that the Strawberries from those gardens were as fine as any that could be produced, and we have evidence of these facts in the prize lists of the London exhibitions in bygone days. In this particular instance fresh beds were made annually, as after the first season the plants deteriorated, although the Strawberry will bear annually for several years from the same plantation in good soils. If fine-looking fruits are required the plantation should not be allowed to remain longer than three years, and in cases where the plants show signs of deteriorating after the second year we should remove them at that time, and on poor gravelly soils every year with a good preparation, as it is possible with good culture to procure large crops annually. In no other way can that fine-looking and highly flavoured variety British Queen be brought to perfection.

Before entering on notes of culture I will give my opinion on the varieties. I believe in growing a good number of varieties, as each has its own particular flavour. In cases where young gardeners are rather doubtful which to plant my advice is to have a trial plantation of varieties of proved merit, make a selection, and act accordingly. As the Editor truly remarks, "the positions the plants occupy have an important influence on the duration of the Strawberry season, early varieties on warm borders and late sorts on northern aspects accelerating and retarding the ripening of the fruit. Varieties:—Black Prince, Early Prolific, Keens' Seedling, Sir J. Paxton, President, James Veitch, British Queen, Sir C. Napier, Unser Fritz, Dr. Hogg, Frogmore Late Pine, and Loxford Seedling. Oxonian is a good late variety, and is grown much in the West of England. I saw it the second week in August at Stoke Edith Park; it was growing on a north border. Varieties for market purposes:—Marguerite, if the market is near home this is a useful variety, as it is very prolific, with large fruits and a good blossom, but as it is rather soft it would not carry well a long distance. If the above variety is not grown, substitute for it Vicomtesse Hericart de Thury; the other two should consist of Sir Joseph Paxton and Loxford Hall Seedling. Varieties for preserving:—Black Prince, Keens' Seedling and Sir Charles Napier; either of these is good, and should be grown in quantity for the purpose. Some gardeners mix the fruit of any varieties that may be in; this I think is unwise, as many, especially of the large-fruited varieties, are not at all adapted for the purpose.

CULTURE.—In private gardens as large a quantity of produce as it is possible to get is required off a small piece of ground, and it pays to cultivate this well. As I have previously stated, the soil in many gardens is the reverse of being good for Strawberries, and it would be ridiculous to treat this the same as market growers would good ground, which it generally is when they go in for Strawberries. Good Strawberry soil requires to be well worked (judiciously of course) if good fruit is required in quantity. I have had first-class Strawberries from plants on ground that was simply dug, but then it was in what is termed good heart, and if Mr. Douglas had simply dug the ground at Loxford he would not have had such crops of fine fruit. Circumstances alter cases, and we must act accordingly. I prefer making a plantation from prepared runners at the end of July, and gather a crop the following season. Some gardeners prefer planting the

runners in beds and making the plantation in the autumn or early spring if it cannot be otherwise done, but by this means a season is lost. The ground should be well worked two spits deep, and have the bottom loosened. A dressing of manure may be given, one at the bottom of the trench and another between the top and second layer of soil. If the subsoil is not of a very good description and of a hungry nature, do not bring it to the surface, but work it over in the bottom, adding anything that may improve it, and keep the surface soil at the top. In heavy clayey soils we should keep the well-worked surface soil at the top, and improve the bottom with turf parings, decayed and burned vegetable refuse. Ground that has been well worked early in the season and has had a light crop growing on it, would not require to be trenched again, but be simply dug and levelled. In either case the ground must be worked sufficiently early that it may settle, and if it is not firm at the time of planting it should be trodden when the surface is dry.

Lay the runners as early as possible into 60-sized pots filled with four parts turfy loam to one of well pulverised manure pressed in firmly, or on pieces of turf. But this should not be used unless it is free from coarse weeds, and has been stacked some time so as to kill all vegetation. By the time the runners are established the bed must be ready for their reception. I do not agree with close planting, as if the plants grow as they should do they would be overcrowded. All the varieties I have named, except Loxford Hall Seedling, which is a compact grower and may be planted 18 inches apart, should be in rows 2 feet apart, and the same distance asunder in the rows, and between every fifth and sixth row the width may be 3 feet, which will allow room for attending to the plants without trampling amongst them. If the soil is not of a very good description, give each plant a shovelful of fresh soil, like that used for the layers, and press it around the ball firmly. A depression may be formed around each plant as a receptacle for water, which would be necessary if the season should prove dry. In summer supply water liberally if necessary, as the plants must be kept growing, and all runners should be picked off as soon as perceived. Employ the Dutch hoe, both to destroy weeds and to keep the surface open. By the end of the season the plants ought to be of good size with well formed crowns; and if the winter is likely to be severe, a top dressing of short, dry, and open manure should be applied. As the plants advance into bloom, and if the weather prove dry, they must receive a thorough watering with either rain, pond, or even sewage or weak liquid manure, and a good soaking of sewage after the fruit has set will be advisable. Just before the flowering period, and after a heavy rain or watering, mulch the bed with long stable litter if it can be procured, which will have become bleached by the time the fruit is ripe. In wet seasons, or even in dry weather if there is time, it is an excellent plan to prop up the fruit from the ground with Birch or Hazel branches. The second season's treatment will consist of removing the runners after the fruit is gathered, and clearing away the loose litter, and in the autumn a dressing of decayed manure on light soils, and a top-dressing on heavy soils, of bonemeal and wood ashes is beneficial. Weeds and runners should be removed, and in the spring treat as advised for the younger plants.—A. YOUNG.

THE Strawberry is one of the most popular fruits. It is the first ripe, is adapted for cultivation in most soils and situations, and its culture of the simplest description. Anyone, in fact, with a plot of ground may grow Strawberries, always subject to certain conditions which I will endeavour to describe as they have been observed in varied soils and situations through a period of nearly half a century.

#### SITUATION.

The Strawberry in this and other countries where found wild is an inhabitant of open woods or copses, and slopes of hills or mountains where it has the shelter of bushes, rocks, or boulders, protection from summer heat and drought by the shade of vegetation, which also affords protection in winter. The plants are never found in hollows where water lodges and stagnates; but on knolls, slopes, or ground through which water passes freely; the ground enriched by fallen decaying vegetation. In cultivation we have, however, to deal with a somewhat different plant. The Strawberry in gardens is an improved, larger, and more useful fruit. Cultivation and selection of the finest varieties has effected much, but this is had at the expense of hardiness, a consequence of cultivation. The Alpine Strawberry is not a whit more hardy under high cultivation than the choicest variety. Plants are hardy in proportion to their vigour. We must give cultivated plants more room than wild, they must have full exposure to light for the elaboration and assimilation of the increased food supplies.

The situation must be open, so that every ray of light will have effect from sunrise to sunset. Shelter is good to break the violence of winds and prevent injury to the foliage, but anything

that detracts from the plants' otherwise full exposure is inimical; shade, except for special purpose being injurious. Hedges are the best shelters, and the alleys or pathways should be alongside the hedges. The best hedge for sheltering a Strawberry plot is an espalier of 4 feet 6 inches height, formed of galvanised wire, No. 13 I.W.G., iron standards pierced for seven lines of wire, with pillar and stay at each end for straining, all galvanised and utilised with Apple and Pear trees on dwarfing stocks. Such take up no more room than a screen of Thorn, Beech, Hornbeam, or Privet, are no more trouble in trimming, and give a profitable return. Screens of this character running north and south 22 yards apart are useful shelters. Walls are the worst possible, as they shade and scorch, and the plants are not so well off as in the open, through the heat and drought incidental to such positions. Hedges appropriate the moisture and nutriment the ground affords for some distance from them, so as to render it of no value for Strawberries. To obtain early fruits plants are sometimes placed in warm borders, due regard being paid to the supply of water in dry hot weather if the plants are to be healthy and afford profitable crops. Ground sloping sharply to the south is selected for early crops, whilst that which slopes north should be chosen to afford late crops.

#### SOIL.

A strong loam is no doubt the best for Strawberries, and especially when of a limestone or oolitic nature. This more particularly applies to the Pine varieties. Any good friable loam liberally manured affords excellent crops of Strawberries. Light and shallow soils are the worst. They are too loose or too hot and dry to render the fruit equal to what it is obtained from soil of a tenacious and moisture-holding character. Very heavy soil is not good, but it may be rendered suitable by burning a part of the underlying strata or clay, and mixing it with the top ameliorated soil, and a portion of the stubborn pan. It may also be improved by dressings of ashes, and by throwing it up roughly to the ameliorating influences of the atmosphere. Dressings of lime are beneficial. Six tons per acre or a bushel per rod is a suitable dressing. Leaf soil, charred refuse, and any loose material, as old mortar rubbish, brick rubbish, &c., are excellent. They assist the percolation of water through the soil, carrying air down with it, the first consideration in making the soil's constituents available as food for plants. In dealing with heavy soils, it is well to loosen the stubborn pan and leave it at the bottom of the trench than to bring a quantity to the surface. Endeavour to retain all the better soil however thin, and add to it by bringing up a little of the poor material at a time, increasing the depth by loosening the stubborn material.

Light soils are improved for any crop by a dressing of clay. A sandy soil on which Strawberries were a precarious crop, was made into a good one by a coating of marly clay at the rate of 100 cartloads per acre. This was applied in winter, thrown about, and dug in early in spring. Shallow soils may be stirred as deeply as we like, but there must not be any attempt at bringing any of the brash to the surface. Clay dressings should always be given on the surface, for clay, like lime, sinks deeper. Lime, or preferably chalk, through holding moisture is an advantageous dressing for light soils, and may be applied at the rate of 20 tons per acre. Gravelly soils require clay. Heavy loams, ditch scourings, and pond cleanings are admirable dressings for light soil—anything, in fact, that increases the depth and is of a moisture-holding character is suitable. Lose no opportunity of bringing in fresh loam, particularly of a heavy nature, for light soils; and road scrapings will improve heavy soils through furnishing the grit they are usually deficient in, and give increased friability.

#### PREPARING THE SOIL.

The soil, whatever it may be, should be stirred as deeply as the good soil allows. Trench just as deeply as there is soil, and loosen the undersoil as much as possible, the deeper the better, but bring none or very little of it to the surface. If manure is required, do not waste it by placing it at the bottom of the trenches. Keep it within a foot from the surface. Ground that has long been under crops and has a rich surface will be the better for trenching, turning the top soil to the bottom and bringing good soil to the surface. This will only need a liberal dressing of manure and exposure to the atmosphere. Peaty soils should have a dressing of lime, and preferably of a magnesian character. Six tons per acre is a suitable quantity. Alluvial soils are the better for a dressing of non-magnesian lime. Soils that have been long under crop and have become full of manure may have a dressing of lime at the rate of 3 tons per acre. Lime should always be used on the surface and only pointed in.

Soil in good heart will not require any manure, it having been manured for the previous crop, but if the crop was an exhausting

one and the ground only fairly good, a liberal dressing of farm-yard manure should be given. Twelve to twenty cartloads per acre is a suitable dressing for land ordinarily cultivated and cropped. Poor soil should have proportionately heavier dressings. It should be dug or ploughed in. Dress ground much infested with slugs with nitrate of soda 1 lb. per rod (30½ square yards), or 1½ cwt. per acre, distributed evenly over the surface prior to planting. Land infested by wireworms may have a dressing of gas lime at the rate of 20 bushels per acre pointed in a little before planting.

#### LAYERING RUNNERS.

Runners of the current or previous year, if spring planting is practised, are the only suitable ones. They are best taken from plantations that have been made in the previous year, and are consequently only a year old. Such afford the earliest and strongest runners, and they have the sturdiest and most solidified growth through their having the advantage of more space than is accorded runners in older plantations, through the parent plants being of smaller size. The runners are best layered in small pots, small 60's or 3-inch; a double or single row of pots as runners are available, being placed midway between the rows and about half plunged, so as to keep the pots steady and insure more uniform moisture. Any good loam will answer for filling the pots, preferably rather rough turfy loam, with a fifth of well-decayed manure intermixed, and a quart each of bonemeal and soot per bushel of soil. Drainage for the pots is not necessary, and the soil need only be made moderately firm in the pots, a space of about half an inch being left for watering. A slight indent is made in the centre of the soil, a runner is placed therein, and secured with a peg. The best is formed of galvanised wire cut about 3 inches long and doubled, but a bamboo cane cut into lengths of 4 inches, split roughly and thrown into water for a few days, can be split with a knife into match-like strips, and these doubled form admirable pegs. They bend readily whilst moist. A small stone may be placed on each runner wire to keep it in position, but these are not nearly so good as the pegs. Cut off the points of each runner wire just beyond the plantlet, unless the variety is a scarce one, when it may be allowed to grow so as to get as many plants as possible. Supply water as necessary, and the runners will be well rooted in about three weeks; but it is well to leave them on the parent plants until the pots are filled with roots, and yet not allowing them to remain until they are very closely matted. They will be well rooted in three weeks to a month or never. Detach and remove them to a north border and keep them moist if the ground is not ready, but the sooner they are planted the better, as they only become stunted through keeping them in the pots. Layering in pots is a troublesome plan; but nothing can be done without labour. Turves 2½ to 3 inches thick, 4 inches wide, and a foot long, inserted half their depth grass side downwards are a good substitute, and are by some considered better than layering in pots. The runners are layered on the turf about 4 inches apart, or 2 inches from the ends of the pieces of turf, and then 4 inches apart as regards the others. If kept moist they will root quickly, and the turves have only to be divided between the runners. This plan even may be too troublesome in some cases, or neither pots nor turf can be had. Layer them in the soil in this case. They will root as quickly as those in pots or on turf if kept moist, and lifted with roots they are admirable for home planting, only keep them as much from the drying influences of the atmosphere as possible, choosing a dull time for planting.

Runners should only be taken from fruitful plants. It is a common occurrence for apparently healthy and at one time fruitful plants to become sterile. Sterile or meagre-fruited plants give the strongest and most runners, and they are selected for sending out and planting. Such are not worth having. They are never to be relied upon, therefore take runners from fruitful healthy plants only.

Nothing pays so well in Strawberry cultivation as a careful selection of plant and a change. Whether the plants get sick of the soil, the climate, or treatment it is difficult to tell. The only thing to guard against is the unfruitful plants, and that can only be ensured by asking for a guarantee. If that is forthcoming a year's growth will soon set things right, for it is not possible to grow Strawberries a year, they being planted in July or August, without proving whether they are fruitful or sterile.

#### PLANTING.

The ground being prepared as advised in the previous autumn or spring (winter is the worst time to work land, or any time when saturated with wet), a crop of early Potatoes may be taken, or preferably Peas—any crop, in fact, that will allow the needful preparation of the ground, which in most cases will only amount to forking, either without or after manuring. If the ground be

light or rough from clods tread it, especially where the rows are to be, but it must not be practised in wet weather. The rows should be 30 inches asunder and 30 inches apart in the rows. This I have found the most suitable for plants that are to remain for any length of time, the plants being put out half the distance asunder in the rows, every alternate plant being cut out directly after the first year's fruiting. In rich deep loam 3 feet apart for the rows and 18 inches asunder in the rows the first year; every other plant being taken out after the first year's crop is gathered is not too much room for the strong growing sorts. For general purposes I prefer the plants in bed-like arrangements for facility of gathering the fruit and cultural requirements. The strong growers in rows 30 inches apart, and the plants 15 inches asunder in the rows the first year and 30 inches the second, leaving a space of 42 inches between every two rows. Moderate growers in rows 24 inches apart, 12 inches the first year and 24 inches the second asunder in the rows, with a yard space between every two rows. Closer planting is not advisable.

Plant just level with the neck so as to cover the roots, and firm the soil about each plant with the feet. If the plants are slightly raised it is better than burying the centre or crown; indeed, that should never be practised. A little care at planting is worth a good many after considerations. Supply water at once to settle the soil about the roots and repeat as necessary. Moist weather is the time to plant. The earlier the runners can be planted the better, which will depend of course on the season, but the middle of July to early August is usually the summer planting season.

Sometimes planting has to be deferred until autumn through the ground not being cleared of other crops, or not cleaned and prepared for earlier planting. September or early October is the latest Strawberry plants should be put out, so that they will have a chance to root and become established before cold weather comes. Spring planting is best effected by taking up the runners when well rooted, and placing them in beds 6 inches apart every way, the beds being of the orthodox width—viz., 4 feet, with 1 foot alleys between them, watering as necessary and keeping them free from weeds. In February or March, as soon as the ground is in good working order, they can be transferred with roots to their permanent quarters, watering if the weather be dry. The best time to plant is when they are starting into fresh growth.—G. ABBEY.

(To be continued.)

#### CHRYSANTEMUMS AND THEIR CULTURE.

(Continued from page 485.)

##### TERMINAL BUD.

A TERMINAL bud is thus named because it is the apex of growth, no other growths starting and growing beyond it like those from crown buds. Terminal buds are the best to depend on for the production of flowers from bush plants and those grown for late use. This bud is not much appreciated by growers of plants for large blooms, because the flowers from buds so formed are much too small except in a few instances. In the north of England terminal buds are formed too late to be of any use for exhibition stands, and for anything else except for late decorative purposes. From few sorts can good flowers be had from these buds even in the southern counties, and practically none in the north. The only varieties I know that are to be depended upon to produce good blooms from terminals are Emily Dale and Sir Stafford Carey. Mr. Bunn, Prince Alfred, and Lord Wolseley often develop flowers of good quality from this bud. This occurs when the crown buds form earlier than the dates previously named for these particular sorts. In that case the crown bud is rubbed out and the growths allowed to extend. Flowers from terminal growths are very compact, but lack the size and solidity of those grown from crown buds, and are not formed early enough for the flowers to be developed in time for the shows except in the cases mentioned. Terminal buds form in a general way in the south from the middle to the end of September, and some even as late as the middle of October, but in northern parts they are not formed till the last-named date. The buds are formed in this way: If the cultivator does not wish to allow the plant or plants to bloom from the crown buds, which are sometimes damaged through various causes, the crown bud is cut off, and the growth shoots which start just below that point are allowed to extend. They in time produce terminal buds. The annexed engraving (fig. 92) represents a terminal growth with buds which was taken late in the season, the side buds having grown slightly too long before being disbudded. As shown by dotted lines, all the flower buds except the centre one at the top are intended to be cut off. This should be done at the earliest opportunity when the centre bud can be plainly distinguished from the side ones, which in their early stages cluster close around the

centre one, and if the attempt to take them off is made too soon the principal one is sometimes damaged in consequence. A small penknife answers best for the speedy and safe removal of the buds. When the plants are grown for decorative or late-blooming purposes the number of flowers retained on each stem must be ruled by the object the cultivator has in view. It should be borne in mind that the centre bud always develops into the largest flower. Useful flowers for cutting may be had from the side buds when a larger number are required.

#### DEFORMED BUDS.

Deformed buds in some seasons are very numerous, and growers of Chrysanthemums are often perplexed as to the cause of such growth. These buds swell to a large size, and instead of unfolding their florets in an even manner they split in unequal parts and become forked and irregular in form. Another kind of deformity

Fig. 92.—Terminal Bud.

is perhaps worse than the preceding one. The buds swell to a large and sometimes unusual size. The hopes of the cultivator are raised at the prospect of extra large flowers. As time goes on and the florets begin to unfold, it is seen that the flower has a confused centre, or, more properly speaking, it has many centres. The florets, instead of all incurving in a central direction, unfold in different ways. In consequence of such deformity the flower is useless. It is difficult to account for such growth taking place in all cases. No doubt it is caused by a check to growth at some stage in the development of the flower bud. The incurved varieties are more liable to produce such unnatural flowers than the Japanese varieties, and more particularly the Queen family is troublesome in this respect, notably Golden Queen of England. The most frequent cause is the "taking of the buds" at too early a period. Sometimes the flower buds will form quite a month earlier than is required. These, if allowed to remain, will produce blooms of the kind I have described. Again, if the plants have been potted in too light a manner—the soil not pressed sufficiently hard into the pot at the final potting—under these circumstances the necessary hard growth required for the production of perfectly formed

flowers is not acquired. The result from such mismanaged operations in potting is abortive blossoms. Flowers of a deformed character are often produced after a very hot and dry summer, consequent upon the plants not at all times receiving the necessary quantity of water at the roots, more particularly after the flower buds are formed. This lack of natural requirements must give a check in some way; therefore I would impress upon all growers never to allow the plants to suffer in this respect. Another reason which causes plants to develop such deformities is when they have been potted in too rich soil and during their growth are fed too highly with strong stimulants, thus causing the growths to be soft, and such growth cannot ripen sufficiently. Some growers think the plants cannot be grown too robustly, but that is a mistake. Strong growth is required, but it must be built up gradually and firmly.

#### REMOVING SUCKERS.

Suckers or offshoots springing from the base of the plants which are grown for any purpose are produced freely from most varieties, still there are some varieties which are shy in throwing up suckers. In all cases if they were allowed to grow they would rob the plants of some strength which should be utilised in a much better manner until the flowers are being produced; after that period no harm is done by allowing the suckers to extend for the production of cuttings. Until the time stated remove all suckers as they appear above the soil. There is a right and a wrong way of performing this trifling operation. Much harm may be done to the plants by allowing a person to do it carelessly. I once learnt a lesson by allowing the removal of the suckers to be done in the wrong way. The regular attendant to the plants being very much pressed for time a youth was set to do this; to facilitate his work he used a long knife and cut the shoots clean out, some of them to a depth of 3 inches under the soil. This, of course, included many roots which grow from the bottom of the suckers, and a considerable check was given to the plants. In careful hands a knife may be used with advantage to cut off the suckers, but the safest manner to remove them is to break them off with the finger and thumb.—E. MOLYNEUX.

#### A CHAPTER ON CELERY.

THERE is no more important vegetable crop than Celery. It is extensively grown in all large gardens, it finds a place in the majority of middle-sized ones, and many cottagers grow it. It plays an important part in cookery, is an excellent salad, and its uses extend beyond this. In large gardens gardeners soon find out that it will not do to treat so important a crop carelessly, and it is very well grown in them as a rule, but amateurs are not always so successful. Some of them raise plants with much care and look well after them until they are put out in the trenches, when watering or earthing up is neglected, and what with proper and due attention might have been excellent Celery is the reverse.

Celery is by no means difficult to cultivate, but it will not bear neglect. It does not need daily attention, but at certain times it requires the performance of a few operations, which are simple in their execution and satisfactory in results. It is attending to it at one time and neglecting it at another, or carrying out one operation and omitting the next, that spoils the crop. It is of much importance that strong healthy young plants be secured before placing them into the trenches. When early plants are wanted to put out in May and be ready for use in August, the seed must be sown in a warm place under glass in March, the plants must be sown in heat until they are several inches in height, and in hardening off they must be treated in much the same way as the half-hardy bedding plants which are put into our flower beds in summer. We plant out about 500 Celery as the earliest batch, these are all raised in heat. The seed is sown in one or two 6-inch pots. The plants are dibbled into cutting boxes as soon as they can be handled. In these they are placed about 2 inches or 2½ inches apart, and they remain in them until they are planted in the trenches. We approve of shallow boxes for young Celery plants as they are convenient to move. In dealing with young plants under glass there is always a danger of their becoming drawn. This may occur by the plants being too close in the seed pots, or through being in too high a temperature and far away from the glass and light. All of these conditions will spoil the plants in a great measure, and they should be avoided. Dwarf plants are particularly desirable. In sowing the seed it is of the utmost importance that the soil in the pots be made firm. In transferring the small plants to boxes, or anywhere else, the soil should also be made very firm. Some weeks ago one of our young men in planting Celery in boxes omitted to press the soil firmly. Another putting them in a few

days afterwards made the soil as firm as he could ram it. When looking over the boxes some weeks afterwards, the great difference in the size of the young Celery plants was very noticeable, the inferior plants being in the light soil. Firm soil is always sweeter than loose material, and the roots produced in the former are more numerous, robust, and close-growing than in the open soil.

Early plants which have been raised in a vinery or Cucumber pit should be placed in a cool frame with the lights on after being brought from the house. In a short time the lights may be removed during the day, then at night, and finally planted out. We have just finished planting our early Celery. From the time the young plants appear until they are placed in the trenches they should not on any account be allowed to suffer for one moment from dryness at the roots, and just before planting they should be drenched, so that the soil may adhere to the roots in quantity. Before planting, however, trenches must be made for the reception of the plants. These may be made in much the same way for both early and late plants. When we want to grow Celery for exhibition and prizetaking, we only put one row in a trench. When it is merely for the requirements of the kitchen or use in the pantry, we grow from two to five rows in a trench. The trenches for the single rows are made from 1 foot to 18 inches wide, and a space of 2½ feet or 3 feet is left between them. The latter are thrown out to a depth of from 8 inches to 1 foot, and the soil is banked up on the wider space between. This is certainly a good deal of space for Celery, but large plants cannot be grown in small space, and we always like to allow of plenty of space for earthing and other attentions. In the case of wide trenches for several rows we allow about 8 inches to each row, a trench for two rows being 2 feet wide and one for six rows 4 feet. The same space is allowed between the trenches, and this holds all the soil that is thrown out in reserve for earthing. We have tried trenches from 6 inches to 18 inches in depth, and the medium ones have given most satisfaction. Our kitchen garden extends to five acres, and during the last dozen years we have tried the Celery crop in various parts of it. In the heaviest soil very large plants were produced, but three parts of them were not sound when fully grown. They appeared all right, but when the stems were pressed hard they gave way and proved pithy or vacant in the centre. Much Celery does this, and it is most objectionable. Such produce may do for seasoning in the kitchen, but it will never do for introducing with cheese or anything in this way, and those who have grown pithy Celery ought to change their practice at once. We had to do so from the heavy ground, and we found it succeed best in light soil. For more than six years we have grown the whole of our Celery in the lightest part of the garden, and pithy plants are never met with. Every one of them are sound and robust, and we are very much gratified with this. The advantage of having it in rather a light soil is not confined to how it grows, but in earthing up the light material suits admirably. A soil half sand or half ashes is excellent for earthing up. The worms do not work in it much, and it blanches the stems beautifully. We do not change our soil for Celery, it is grown on the same piece year after year, and will be so as long as it turns out as good as it has done. Agree, then, to make the trenches on the lightest of soil in the garden and get them ready. We always form our trenches in March or April, that we may use the ridges and plant them with Lettuce, Spinach, or other quick-growing crop that will gain maturity and be cleared away by the time the plants require earthing up.

The question of manure comes next. After trying all sorts, natural and artificial, we prefer that from earth closets to any. It is astonishing how very well this suits Celery, and the plants it produces are first rate. The way we apply it is this. Dry soil is mixed with it; as it is taken out it is spread along the bottom of the trench to the depth of 4 inches, then it is forked in, and after that a layer of good soil and old Mushroom bed refuse or something of that sort is spread on to the depth of about 3 inches, and the Celery is planted in this. It is some little time in finding its way into the manure that has been forked down into the bottom, but when it does it makes astonishing progress. In planting, each one is lifted very carefully, and the hole for the roots is made large enough to admit them without any cramming into a small space. As soon as the soil is put back, and when the Celery has been planted, the soil is trodden down as firmly as it is possible to make it, then the plants are watered thoroughly. Should the weather be dry it is watered again in a few days, and in a fortnight or so the soil is again trodden and watered. The plants, we find, root much better and grow more quickly when the soil is firm in the trenches than when quite loose, and we attach very great importance to having the soil firm. The early batch should be put out in the way indicated at once; and those who wish to

possess late plants, as well as others who have no means of raising them in a hothouse, should give them attention now. If any rough frame is nailed together and put down in a warm corner, and the interior filled with lawn mowings, leaves, manure from the stable or pigsty, a slight hotbed will be the result, and if the seed is sown very thinly on this the young plants will soon appear, and by thinning out some of them the bulk may remain until transferred to the trenches. A quantity of rich soil should be spread over the manure in which to sow the seed, remembering to make it firm, and if this seed is sown by the middle of May the plants will be ready for the trenches by the end of June or early in July. This represents the case of those who have no glass in their gardens. Where there is a frame or glass house of any sort, the pot system of sowing the seed should be practised for main crop or late plants, and as soon as they can be handled make up the slight hotbed and plant them on the top of this for a few weeks. They need not be protected on the top, and if put in about 2 inches apart in good rich firm soil they will soon make excellent dwarf plants. As a rule, there is never enough rain at the time Celery is planted to dispense altogether with artificial watering, and this should be practised very frequently until the plants have been earthed up once, when the extra soil put on the top of the roots in doing this will keep them cool and moist.

Premature seeding is a fault often experienced in Celery culture, especially during the early stages of its growth; but for years past we have not lost a plant in a thousand from this cause, and we attribute this success to the firmness of the soil in which the roots are growing and never allowing them to suffer or be checked by want of water. It is only careless culture and neglect that cause plants to "bolt." Where watering cannot have the attention it requires in very dry weather the surface of the soil between the plants should be mulched over with short manure to prevent evaporation and keep the roots cool. Celery planted in May will require earthing up early in July, but this is an important operation often neglected, especially in small gardens. When the plants are not earthed they spread out, and the largest of the leaves are apt to weigh down and break over. The first and second earthings would prevent this, and they at least should be applied. We begin earthing when the plants are about 1 foot in height. The smallest of the side leaves are taken off before beginning to add any soil, and the earth is broken very fine before putting it amongst the plants. It is pressed firmly round each with the hands, and when all is put round it is trodden down with the feet. The main point to avoid in earthing is never to allow any of the soil to fall into the centre of the plants. A piece of matting tied round each plant before earthing will generally prevent this. When we wish to secure sticks of unusual quality we earth them with finely sifted coal ashes mixed with light soil and a little lime.

—A KITCHEN GARDENER.

## ORCHID NOMENCLATURE.

It has been announced that a part of the programme of the Royal Horticultural Society at the Liverpool Show will be a conference of orchidists respecting nomenclature, and as this is likely to be of some importance a few preliminary observations may be appropriate.

No official statement has been made as to what is the special object of the Conference, but it may be assumed that it is intended to point out the defects of the present system and to substitute some preferable method, or to draw up regulations to guide those who name Orchids. There is plenty of room for the improvement of horticultural nomenclature generally, and in the case of the Daffodils the consideration given to the subject by the committee appointed for the purpose has had good results. It may, therefore, be hoped that something equally satisfactory will follow the Orchid Conference, but the subject is a more difficult one, and last year no progress was made in the matter. Mr. W. Lee and Mr. Harvey then thought that nothing could be done without the presence of Professor Reichenbach. Mr. F. W. Burbidge, Mr. R. I. Lynch, and Mr. James O'Brien were of opinion that the subject might be discussed by the Conference committee, but it was ultimately agreed that the question should be deferred. The assistance and opinion of the great orchidist would undoubtedly be most valuable in deciding what course to take, but in his unavoidable absence the committee must depend upon themselves, and there is no reason why they should not at least be able to clear away some difficulties.

The general system of nomenclature in the Orchid family should be formed in a similar manner to that adopted for other plants, which is now clearly defined and accepted by most botanists. The best and most authoritative exposition of this subject is to be found in the "Lois de la Nomenclature Botanique," by M. Alphonse De Candolle,

of which an English translation was prepared by Dr. H. A. Weddell and published by L. Reeve & Co., Covent Garden. The rules given in this treatise were adopted at the International Botanical Congress in Paris, August 1867, when there were about 150 botanists present, and they, therefore, represent the opinions of the principal European authorities. Commenting upon the necessity for some recognised system, M. De Candolle refers to the enormous number of synonyms which had gradually accumulated. Thus in Steudel's "Nomenclator" for 1821 "there were 55 synonyms for every 100 admitted species. The second edition of 1840 gives the proportion of 75 to 100," and the index to De Candolle's "Prodromus" a few years later gives 102 synonyms for every 100 accepted species. This is alarming, and affairs are not much better amongst the Orchids; but it will be beyond the power of the committee to rectify evils of this character, though they could impose some restrictions upon the names to be given to new species or varieties. Two introductory rules in the treatise already mentioned are the following, and are well worth attention:—"The rules of nomenclature should neither be arbitrary nor imposed by authority. They must be founded on considerations clear and forcible enough for everyone to comprehend and be disposed to accept. The essential point in nomenclature is to avoid or to reject the use of form or names that may create error or ambiguity, or throw confusion into science." The former of these rules all will accept, and the latter as applied to Orchids will probably constitute the chief subject of discussion. Sometimes in making alterations with a view to rectify previous errors the difficulties are only increased, and it behoves all who propose the abolishment of names that have been generally accepted, to have good reason for the course advocated. "No one," says M. De Candolle, "ought to change a name or a combination of names without serious motives derived from a more profound knowledge of facts," and again, "No one is authorised to change a name because it is badly chosen or disagreeable, or another is preferable or better known, or for any other motive either contestable or of little import." In the bestowal of names upon new species or varieties, however, the matter is different. All these points should be borne in mind. The name selected should not be too long or difficult to pronounce, it should not be adopted "from a barbarous tongue," and it should "in general indicate something of the appearance, the characters, the origin, the history, or the properties of the species. If derived from the name of a person it usually calls to mind the name of him who discovered or described it, or who may have been otherwise concerned with it." A glance at any list of Orchids will show how little these rules have been regarded in their nomenclature. Such names as *Vrydagzenia* and *Wulschlaegelia* have little to recommend them, though happily that is of no consequence to horticulturists, as the plants bearing these titles are at present confined to the care of botanists. The desire to honour various persons by bestowing their names upon Orchids appears also to have become very general, for we find that over 600 species and varieties of the Orchids in cultivation bear the names of individuals who have possibly distinguished themselves in some way, though not always by discovering, describing, figuring, or studying the plants with which they are associated. Yet M. De Candolle considers one or more of these qualifications necessary to render a person worthy of the honour. The Conference might well give some attention to this matter, and a decision restricting these honorary designations within reasonable limits would be a valuable service.

The species must, in a great measure, be left to the botanists. Only those fully competent, with ample material for reference, should attempt to bestow new specific names upon fresh introductions. Horticulturists have, however, to deal with a great number of varieties, and it is in regard to these that the chief difficulties are now experienced in naming Orchids. Botanically, many species admit of several sub-divisions, each bearing its proper title, but in horticulture this is occasionally inconvenient, and leads to a multiplication of names that is almost overwhelming, as is seen in the titles of some varieties of British Ferns. Amongst such plants as Roses, Pelargoniums, Dahlias, Carnations, Auriculas, &c., which have been very popular in British gardens, and are increased in numbers from seed, botanical names have been discontinued, and English or local designations adopted instead—a plan well adapted to their case, as it is also to the garden forms of Daffodils and any other plants that are similarly readily increased from seed. This is quite in accord with the "Laws of Botanical Nomenclature," for it is there stated that "Seedlings, half-breeds of uncertain origin, and sports, should receive from horticulturists fancy names in common language, as distinct as possible from the Latin names of species and varieties." Of late, however, an attempt has been made to use the "fancy names" for varieties of Orchids, and it requires very careful consideration before giving support to a practice that is open to several objections under such different circumstances. The *Cattleyas*, the *Lælias*, the *Odontoglossums*, and the *Masdevallias* are the most prolific of these puzzling varieties, but it must be remembered that all these are intro-

ductions, none is of garden origin except the home-raised hybrids, concerning which there is no difficulty. Take for example *Cattleyas Mendeli*, *Mossiae*, and *Trianae*, every importation of these contains forms differing in some points from others, and it is almost impossible to find two plants precisely alike. Sometimes the differences are considerable, and then a really distinct variety is worthy of a name which has previously been bestowed in accordance with botanical usage, mostly Latin adjectives indicating some particular quality of size or colour. In some trade collections only the choicest are thus distinguished, and the relative merits of other forms not sufficiently well marked to merit a name are indicated by crosses on the labels. The same may be said of *Odontoglossums crispum*, *Pescatorei*, *cirrhum*, and others, the very finest forms of which are only honoured with names. If this were adopted there would be no danger of names becoming too cumbrous or troublesome, and it is quite within the province of the Floral Committee of the Royal Horticultural Society to refuse to award certificates to plants bearing objectionable names. On the other hand, if these "fancy names" are admitted there is a danger that we shall be flooded with personal designations, "Souvenirs," &c., like those applied to Roses and Chrysanthemums, and which will be given to varieties of quite a different classificatory value. As regards the last named plants, for instance, Chrysanthemum Mrs. George Rundle is sufficient, so is Rose A. K. Williams; but Orchid Duke of Marlborough is not sufficient to distinguish the plant, and we have to say or write the full title *Cattleya Mendeli* Duke of Marlborough, for which at least the merit of brevity cannot be claimed. Further, the "fancy names" indicate that the plants are of garden origin, whereas the Orchids are simply wildlings, and as much entitled to be considered botanical varieties as many other plants. There is another point to be considered, and that is that some scores of varieties have already received botanical names of the ordinary character. If the "fancy name" system be adopted, to render it consistent these ought to be abolished and others substituted, otherwise we should have a strange mixture of titles applied to forms of one species of equal value.

Hybrids are usually indicated by a cross placed before the generic name, but the method advocated in "The Laws" is far the best for showing the origin of the plant when this is known; thus *Amaryllis vittata-reginae*, which indicates that it has been raised from *A. reginae* fertilised by *A. vittata*.—L. CASTLE.

At a general meeting of the ROYAL HORTICULTURAL SOCIETY, South Kensington, S.W., held June 22nd, Charles Noble, Esq., in the chair, the following candidates were unanimously elected—viz., Hamilton Gordon, Luigi Ricci, and Robert Thomson.

— A CORRESPONDENT writes in reference to the PROVINCIAL SHOW OF THE ROYAL HORTICULTURAL SOCIETY:—"Those of your readers who intend visiting Liverpool next week and desire to see some of the grandest railway scenery in England should, as far as may be convenient try the Peak route through Derbyshire, the Midland Company's line and gardeners who desire to see Chatsworth will find Rowsley station the most convenient.

— WE have received from Mr. Laxton of Girtford, Bedfordshire (the successful originator of many fruits and vegetables) fruit of NOBLE, an early Strawberry remarkable for size and excellence. The fruit is very large, 2½ inches in diameter, ovate in shape, and slightly corrugated. The skin is smooth, strewed with small seeds on the surface, shining and dark red in colour. Flesh deep crimson, rather soft in texture, briskly flavoured, and of good quality. This is a very handsome fruit. It was raised by Mr. Laxton from Forman's Excelsior, is very early, coming in three days after King of the Earlies, is a vigorous grower, hardy, and a free bearer, producing few small fruit.

— IT appears that though the season is so late, RHODODENDRONS flowered about their usual time—at least, such was the case with Mr. M'Intosh's great collection at Duneevan. Calling there a week ago, practically all the flowers were faded, the freshest of all then remaining being Warrior. Nor has there been the usual marked difference between the early and late sorts as to time of expansion, but all seem to have practically opened together, and the display has been on the whole excel-

lent. The Liliams amongst them are now advancing; they are not so tall as usual owing to the cold weather, but sturdy and promising to flower well, *L. Krameri* having nine buds on one stem, a number that we do not remember having hitherto observed. Though Mr. Mcintosh's health is very far from being such as his many friends desire, they will be glad to hear that he has been able to enjoy his garden of late when the weather was favourable for outdoor exercise.

— A CORRESPONDENT, "J. W. H.," desires to be informed as to the best way of PRESERVING PEACHES in their whole state, and as near ripe as possible. If there is any other than the ordinary way of bottling them, he will be glad to have particulars. We will readily publish any information on this subject that may be sent for that purpose.

— THE second edition of the OFFICIAL GUIDE TO THE MUSEUMS OF ECONOMIC BOTANY, ROYAL GARDENS, KEW, has just been issued. It is devoted to the Dicotyledons and Gymnosperms, the guide to the Monocotyledons, which are grouped in No. 2 museum, not having been prepared yet. This issue has been revised and increased by the addition of twenty pages, giving a variety of information relating to the uses and properties of plants.

— "A." writes—"The late MR. R. KYRKE PENSON of Denbam House, Ludlow, who died May 22nd, aged seventy, was well known as one of the National Auricula and Carnation Society's supporters, also as a grower and exhibitor of Auriculas, but to the horticultural world he was less generally known as a professional architect and an able landscape artist. Some of his pictures have been exhibited in London, and gained him considerable reputation."

— BEDS of the very fine variety *VIOLA QUEEN OF LILACS* are now in full beauty at the Botanic Gardens, Birmingham, in the *Viola* garden, where it shows how superior it is to the old "Blue Bell" for bedding. It is a stronger grower, of excellent habit, with larger flowers and brighter colours, and of sound constitution, as it will stand very hot summers and very severe winters. It is one of Mr. W. Dean's many fine seedling varieties sent out a few years since.

— "W. T." sends the following note on BLACKBIRDS:—"In a garden near me at The Cottage, Mount Vernon, a pair of blackbirds built their nest early in January amongst the Ivy near the kitchen window, from which the birds were regularly fed. Notwithstanding the inclement season, the fifth brood was batched out end of May. In the same garden I observed rather novel-looking borders, composed of champagne bottles turned upside down. A hole was broken in the bottom of the bottle with a chisel, then filled with earth, in which were planted *Sedums*, *Saxifragas*, *Echeverias*, &c. They looked pretty in woods and round rockeries when placed in a diversified manner."

— MASDEVALLIAS FOR BUTTONHOLES, &c.—"W. D." writes:—"I think the varieties of *M. Harryana* will before long become prominent features for decorative work, for they are so easy of cultivation, are such profuse bloomers, and are so very beautiful in the richness and variety of colours, that before long we shall find it a Covent Garden plant, and in great demand in a cut state, for they can be kept in good condition so long after they are cut. At the recent Orchid Exhibition at the Botanic Gardens, Birmingham, a special class for *Masdevallias* brought out a beautiful display; and just now Mr. Latham has in the Botanic Gardens a number in bloom. When the market growers take this plant in hand, as they will do by-and-by, it will become one of our most popular decorative indoor plants."

— THE time has now arrived when an estimate may be made of the FRUIT CROP IN KENT. Red and Black Currants have thinned lately through the cold east winds; the Dutch Blacks are the best. Cherries a large crop, but dropping. Plums and Damsons will be an average crop. Apples and Nuts are very short, and are much infested with maggot and caterpillar. Gooseberries are plentiful and cheap, Apples scarce, Pears fair. Owing to the general depression in agriculture and trade Kentish fruit-growers do not look forward very confidently to realising good prices for their produce.

— THE monthly meeting of the BELGIAN HORTICULTURISTS was held in Ghent on the 14th inst., those present comprising MM. Blanckaert, Arth. Desmet, Louis Desmet-Duvivier, V. Cuyelier, Bernard Spae, Moens, A. Rosseel, Edm. Vervae, Ch. Van Geert, and J. Cloisin; M. James Bray presiding and M. Alex. Dallière was Secretary. Certificates of merit were awarded for *Fagus atropurpurea tricolor*, from M. Ed. Pynaert-Van

Geert; *Pandanus discolor*, shown in flower for the first time on the Continent by MM. Jacob Makoy & Cie. of Liege; *Masdevallia macrantha*, from M. Aug. Van Geert; *Cypripedium grande* and *Cattleya Mossiae*, from M. Jules Hye-Leysen; *Odontoglossum Pescatorei* var. and *Vanda insignis*, from MM. Vervae & Cie.; *Sambucus canadensis filicifolia*, from M. Ch. Van Geert, d'Anvers. A cultural certificate was awarded for *Odontoglossum vexillarium*, from M. L. Desmet-Duvivier, and honourable mention for *Caragana sanguinea*, from MM. Jacob Makoy & Cie. of Liege; *Elaeodendron (Aralia) Chabrieri*, from M. Ed. Pynaert-Van Geert; *Pavetta montana*, from M. Desmet-Duvivier; *Phoenix senegalensis*, from M. Bernard Spae; *Croton Gladstonei*, from M. Alex. Dallière; *Ceanothus americana flore pleno*, from MM. Fr. Desbois & Cie.; *Sobralia macrantha nana*, from M. Aug. Van Geert; *Cattleya Mossiae* var., from MM. Vervae & Cie.

— MR. B. S. WILLIAMS' EXHIBITION OF ORCHIDS at the Victoria and Paradise Nursery, Upper Holloway, still continues very attractive, the fine plants of *Laelia purpurata* making a handsome display. *Cypripediums* also add considerably to the number of flowers, *C. superbiens* being beautifully represented by well-grown plants with large flowers, the dorsal sepal regularly striped with green, and the petals bearing numerous dots. The white and useful *Dendrobium Dearei* is in capital condition, one exceptionally fine plant having twelve racemes of four and five flowers each. As these flowers last well when cut the plant is likely to become a favourite wherever white flowers are in request. The white *Phaius Marshalli*, the peculiar reddish *Anguloa Ruckeri sanguinea*, and the strange green-flowered *Cynoches chlorochilon* are flowering, the latter being a very remarkable Orchid, with a long slender curved column similar to some others in the "Swan Neck" genus. *Maxillaria grandiflora*, with wax-like flowers, the sepals and petals white, the lip brownish yellow, is notable. *Saccolabium retusum* has some handsome racemes of flowers. The distinct *Cypripedium Druryi* is not seen very often. The flowers are of medium size, of yellowish tint, striped with brown down the centre of each. *Odontoglossums* are numerous. *O. cordatum* and *O. luteo-purpureum* are represented by strong plants of good varieties. The graceful little *O. Ehrenbergi* is also flowering; it is apparently intermediate between *O. Rossi* and *O. cordatum*, with narrow tapering sepals thickly spotted with pale brown on a white ground. The petals are broader, white or very faint blush, with a few spots at the base; the lip is similar, but with an undulated margin and without the spots. The flower-stalks are very slender, and the plant has a pretty appearance.

#### RED SPIDER ON MELONS.

"DISCRETION is the better part of valour," and I would impress this on the minds of those who have not used sulphur for the destruction of red spider. I have found that if the pipes are painted with sulphur when they become warm the fumes, if strong enough to kill the spider, will kill the Melon plants; also if the walls are whitewashed and the sun shines on them the fumes are injurious. I once had to hold up the leaves of some Melon plants whilst the foreman blew sulphur on with the fumigating bellows. The result was a six-light pit of dead plants before forty-eight hours had elapsed.—J. GADD.

#### CHOICE PERENNIALS IN FLOWER.

THE spring and early summer months are decidedly the richest among hardy herbaceous, alpine, and bulbous plants, and in a few remarks respecting them at their season of flower I have placed them collectively under the heading of "Perennials." So great is the variety of flowering perennials which any border 100 yards long may contain, and so many of which are of such great service in a cut state, that it is surprising herbaceous borders are not oftener met with in private gardens. Surely there is sufficient scope for their accommodation, and apart from the intrinsic value of the plants the abundance of flowers which they yield, to say nothing of the attractiveness of such a border at the present time, would well repay any moderate outlay. I do not refer to what too often bear the name of herbaceous borders in many establishments, and which contain a fair complement of plants, giants far better suited for mingling in shrubbery borders, and at the same time make room in the herbaceous border proper for really good and select plants, of which there are abundance, for I have no hesitation in saying that hardy plants were never more popular, nor were they ever grown in greater numbers than now. Another point may also be gained by having a good collection of hardy perennials in all establishments, by a suitable arrangement in the first place, and then in a clear and well defined hand place its full name in front of each. If this were adopted a little more frequently than it is we should see a greater number of the rising generation of young gardeners possessing a knowledge of the plants, who are unfortunately in many cases entirely ignorant in this respect. Still, it is so, and so little really is known of the best of our hardy perennials that many young gardeners and not a few old ones have from tuition been accustomed to regard hardy

plants as something akin to weedy straggling rubbish, and not worth the room they occupy. In my experience this has frequently been the reply when I have been endeavouring to persuade a friend or acquaintance to attempt the culture of a few of these plants, and in the cases where I have succeeded in persuading them, which are not a few, their only regret has been that they were not aware sooner of the really good plants which are so plentiful. I will conclude these preliminaries by remarking that I consider a collection of hardy plants should find a place in all gardening establishments.

Among bulbous plants yet in flower may be mentioned the double Poet's Narciss, *N. poeticus* fl.-pl., in which we have a flower of pearly whiteness with fragrance unsurpassed. There appears difference in form even of these, some strains being as fully double as a Rose to use a common expression, and others only having a double number of petals. Of course everyone will decide in favour of the former who requires a flower of durability. From rather late-planted batches of poeticus quantities of flowers have been taken, and the same remark applies to *N. biflorus*, while *N. schizanthus orientalis* has been past a week or more. This latter is very pleasing in a cut state. It may here be observed that the season of flowering of these and other bulbous plants may be considerably prolonged by successional plantings, which, beyond supplying a more lengthened display, will materially deepen the interest already involved.

Two other charming bulbs just now are to be found in the genus *Allium*, in which *A. triquetrum* and *A. neapolitanum* are represented. The former is a most pleasing species, not quite 1 foot high, but certainly a most desirable and interesting plant. The flowers are arranged in drooping umbels somewhat bell-shaped and pure white, and in the centre of each petal an exceedingly narrow line of light pea green. This combination of colour does not usually meet with many admirers. In the present case, however, it is the exception, for all who behold it speak highly of its ornamental characters. The latter plant also has white flowers, which are very useful for cutting, as is the first named. There is not much in blue flowers just now among bulbous plants. The *Scillas* or *Squills*, both of the nutans and campanulata sections, are passing out of flower. They have, however, been very charming, and for grassy slopes or naturalising they are valuable. In both groups are to be found rose, white, and blue flowers, the latter colour being represented by several shades.

Speaking of blue, our thoughts very naturally turn to the *Gentians*, in which genus this colour predominates, and what more striking when seen *en masse* have we than the intense blue of its flowers, which are always so bright in the morning sun? But how shy this plant is of flowering in certain localities, while in others small tufts may be found almost hidden by its large erect bells of blue. Often have I recommended firm, very firm, planting for this, and, in fact, any of the family with compact tufts of leaves, and I still advocate and practise it. Only this day, June 3rd, have I planted a small patch, and not content by exceptional firm planting in the first place, I took a spade and beat the whole surface hard, plants and all, which, owing to the coriaceous texture of its leaves, do not appear to suffer the slightest injury therefrom. This circumstance, which I have always regarded as a valuable hint towards good culture, dawned upon me some twelve years ago owing to a quantity of it then used as an edging flowering more freely than the clumps in the middle of the bed. The outer ones were nearly always being walked upon, except when in flower, so that the ground became as hard as a well trodden path, and through this hard surface the stoloniferous growths issued abundantly, and it is due to this accidental though valuable lesson that I have purposely trodden many hundreds. I find, however, that it flowers quite well without all this care in some soils, but in clayey and cold soils it is shy, and from my own experience it flowers most freely when situated in light sandy or turfy loam and peaty soils, and especially so if the subsoil be of gravel. The same may be said of the Vernal *Gentian*, a delicious bit of blue, which the artist really delights in reproducing.

The Grape Hyacinths are on the wane now, though they constitute when in flower a most pleasing group of dwarf spring bulbs, which last for weeks in succession; and who, I wonder, would wish his garden to be devoid of that lovely colour to be found in *Omphalodes verna*, a plant which for shade moisture is most delightful? Spreading out into large tufts, or rather broad carpets, and studded with its brilliant blue flowers, few plants are more enchanting than this modest beauty, and few rejoice more in cool and shade than this and the pretty white variety which forms so fitting a companion for it. I have the latter at the present time behind a low brick wall where the sun never reaches it, and nothing could be more perfectly happy than it appears to be, and which its luxuriance fully illustrates.

But yet another bit of blue may be found in that charming little rock shrub, *Lithospermum prostratum*, than which we have few finer plants for adorning our rockeries. It delights in a sunny position and not too much exposed, and where its tiny fibres may go down deeply into good soil. It should be well planted in the first instance, for it is one of those plants which cannot endure being removed, as the twiggy fibres do not hold the soil, hence the danger. The first season or two after planting it should receive attention, or it may become straggling and thin. This is overcome by cutting it back immediately after flowering, when it will form abundant growth from the centre before autumn arrives. These young growths when 2 inches long may be detached with a heel, and if inserted under a handlight or bellglass root freely, such cuttings as these generally making good plants; and seeing we cannot have too much of such a one, its propagation may freely be indulged in, and may be used as an edging with very good effect.

Of plants bright and conspicuous in the flower garden just now we have nothing to compare in any way with *Primula japonica*; its stout bold stems, on which are arranged its whorls of crimson magenta flowers, are simply unique. I need hardly add that a plant so telling individually is a glorious sight when a number is seen together; and even after an acquaintance of some years, an intimate acquaintance too, I have never seen it so near perfection as when viewing it this week, when it attracted attention at a distance of about 80 yards. So rich and so intense were its massive spikes of flowers, towering above abundant and vigorous foliage. This is a glorious plant for the moist bog garden in full sun or a moist border in partial shade, and it may be well to observe that none of the variety known to me appear to approach in intensity of colour that of the original plant. In its genus it is unique, and in the flower garden and herbaceous border at this time it holds a similar position.—J. H. E.

(To be continued.)

## AMMONIA IN FRUIT AND PLANT HOUSES.

I WAS under the impression that the value of ammonia in the atmosphere of fruit and plant houses was understood by gardeners generally. I know that many of the best fruit-growers practise it with beneficial results. Fresh stable manure, which has been turned a few times so as to dispose of its noxious vapours, is very valuable for surfacing the inside of fruit houses, and if this can be renewed a time or two before the fruit commences ripening it will be all the better. A little guano placed occasionally in the evaporating troughs is very beneficial, but this must be applied with caution or the reverse would be the case. We have placed a large pot filled with cow and horse-droppings and soot in Cucumber and Melon houses. This was stirred up every afternoon when the house was damped down and closed, and beyond question the plants enjoyed it. Some of the finest plants of *Gardenias* I ever saw were grown in a dung-heated pit; the foliage was almost "black with health," and the plants bloomed profusely. Where stove plants are grown the centre of the house is often occupied with a stage of either wood or slate, but I am quite certain a pit which could be filled with prepared stable manure and leaves, leaves alone, or even tan, would be far better for the plants.—A. YOUNG.

I, LIKE "F. H. W." (page 481), felt disappointed that no one supported Mr. Iggulden in his views respecting the value of ammoniacal vapour in vineries. Speaking for myself, I have found most beneficial effects from the use of it, as I believe it is a great check to red spider. When I have been able to get liquid manure from the drainings of cow sheds or stables I have used it without stint both in vineries, Peach houses, and more especially for Cucumbers and Melons, of course being careful in using it when the foliage is very tender or the Grapes in bloom. I once was inclined to think that it was the cause of some Grapes rusting when used liberally when they were in bloom, and thus was cautious ever after. When natural liquid manure is not obtainable I sprinkle a handful of guano on the floors after they are damped down, the fumes at times causing a person entering the houses immediately after to sneeze; but this soon goes off, and by leaving a little ventilation all night the houses are as sweet as can be desired in the morning. Time will not allow me to say more on the subject, but I must say Mr. Iggulden has hit the right nail on the head for success in Grape-growing by his advocacy of ammonia in vineries.—J. GADD.

## LIVERPOOL—VISITORS' GUIDE.

(Continued from page 482.)

FROM the nursery last mentioned directions should be obtained for the residence of E. Harvey, Esq., Riversdale Road, Aigburth. I think Otterspool the best station for this establishment. Mr. Lindsay would be able to give the necessary instructions, or visitors would obtain them from the nursery named. The garden is famous for alpine and herbaceous plants, and also for a large and varied collection of Orchids, Mr. Harvey being remarkably fond of both classes of plants. The gardener is Mr. Bostock. In a large measure Mr. Harvey's energy and perseverance have assisted in gaining support for the coming Royal Horticultural Society's Show at Liverpool.

I may here state what I have omitted to say while at Wyncote and Calderstone. From this point about twenty minutes' walk will reach Cleverley, Allerton, the residence of T. S. Timmis, Esq. (gardener, Mr. B. Cromwell). The glass there is comparatively new, and comprises a number of plant and fruit houses all leading from a long corridor. This arrangement is, perhaps without exception, the most compact and convenient within a considerable distance of the city. Mr. Cromwell being a good gardener, will be certain to have something good on view by the date of the Show, the houses only just being furnished at the time of my last visit. The arrangement of the houses alone is well worth a special journey from Liverpool to see.

About twenty minutes' or a half an hour's walk from there is Allerton Priory, the home of J. G. Morris, Esq. (gardener, Mr. W. Tugwood). There is a large extent of glass in these gardens, both for the accommodation of plants and fruit. Mr. Tugwood has been a successful exhibitor at the Liverpool shows for some years. Close by are Allerton Towers, the seat of Sir T. Earle, Bart. (gardener, Mr. J. Storey). The principal feature is the Peach range. Directions for reaching these should be obtained from Mr. Cromwell.

We start from Garston again, on the Cheshire line. The journey should be broken at Hunt's Cross, the next station, for the purpose of inspecting the gardens at Woolton Wood, where Halbrook Gaskell, Esq., grows his famous collection of Orchids, which is the largest private collection in this neighbourhood. The gardens are twenty minutes' walk from the station, and in addition to Orchids there are to be seen collections of Ferns, a pretty fernery, alpine and herbaceous plants. Only a few minutes' walk from the front entrance to Woolton Wood is Camp Hill, the home and gardens of F. H. Gossage, Esq. (gardener, Mr. J. Jellico). This is certainly worth seeing, for Mr. Jellico does things wonderfully well, and has been one of the successful competitors at Liverpool for some years. Leaving here Gateacre station should be steered for, which is twenty minutes' walk from Woolton. The line taken is straight through the village and on until Gateacre Brow is reached, which is the first road on the right, and leads to the station. Upon entering the Brow the residence of Sir A. B. Walker, Bart., is on the left-hand side, but to enter this place it is necessary to pass the entrance to the Brow a few hundred yards, the house and gardens being then on the right. Mr. Glover is the gardener, and will be known to many from his position for a time as Secretary of the Liverpool Horticultural Association.

From Gateacre the train should be taken for West Derby, which is

twenty minutes' walk from the village. No one will be disappointed by paying a visit to this fine place, for it will be found perfectly clean. It is one of the most extensive gardening establishments, and perhaps the best kept garden in Lancashire; it, however, is decidedly the best in the neighbourhood of Liverpool. Mr. B. Barham has charge of Croxteth gardens.

Knowsley Hall must not be omitted, for it is the most extensive garden about Liverpool. It is four miles from West Derby, and when at the Earl of Sefton's, if permission can be gained to pass through the Park, Knowsley will be reached in half an hour's brisk walk. It can, however, be reached by the London and North-Western railway from Edge Hill or Lime Street station to Huyton station, from which it is two and half miles. This is rather a long walk, but the acres of *Rhododendron ponticum* growing naturally on the moss, when all are in bloom, form a beautiful sight, and one that is not quickly forgotten. Gardeners must visit Knowsley, for they will be well repaid for the walk necessary to reach this gigantic gardening establishment. When at Knowsley ask Mr. Harrison to direct you to Mr. Whittaker's Cucumber-growing establishment; it is not far away on the Knowsley estate. In this establishment Cucumbers are grown without ventilation, and tons are cut weekly.

One more trip for a change will be detailed, and then I close this

Fig. 93.—NORRIS GREEN.

the third one after leaving. It may not be convenient to venture on to West Derby if the day has been fairly spent in visiting the places referred to. This, however, is a matter for each individual to decide for himself. West Derby can be reached by trams from town for 4d., which pass Lime Street station every quarter of an hour. Visitors often make a mistake with these trams, because there are others with West Derby Road upon them, but these are of no service for the traveller to West Derby. The trams are green, and have the name on the front as well as the back. The Green Lane tram will do very well, it passes the same place, and by it passengers should pay to Tue-Brook Railway bridge, and then follow the same 'bus a few hundred yards—namely to Green Lane Corner, where it turns from the main road and passes along another to the right. Wait at this corner for the West Derby tram, and ride until it stops in the centre of the village. West Derby can also be reached by train from the Central, fare 5d., third class, although this line goes on through Garston, many of the trains reach West Derby in a little more than half an hour. When the tram is left in the village of West Derby ask for Norris Green (fig. 93), the drive gate being in a straight line for the village, and only five minutes walk from it. Everybody can tell the stranger the way to Norris Green, the name of which, as well as that of the gardener, Mr. W. Bardney, is well known to the readers of this Journal.

From the village of West Derby will be seen the lordly entrance to Croxteth Hall, the seat of the Earl of Sefton (fig. 94). The gardens are

"Gardener's Guide" for Liverpool. From Lime Street, or from Birkenhead, the station close to where the tram starts for the Park, Chester may be reached; from the former the fare is 1s. 9d., and from the latter 1s. 5d. The two largest provincial nurseries in this part of the country are side by side in the vicinity of the old city of Chester. The Newton Nurseries (Messrs. James Dickson & Sons) are ten minutes' walk from the station, and the Upton Nurseries, those of Messrs. F. and A. Dickson & Sons, twenty minutes. A 'bus runs to the latter from Eastgate Street. These Nurseries are well worth visiting when in the neighbourhood of Liverpool. While at Chester, Eaton Hall, the residence of the Duke of Westminster, should be visited. This is four miles away, but a 'bus leaves the tram offices close to the station for Eaton Hall daily, starting at 2 P.M. and returns at 5 P.M., return fare 1s. 6d. Steamers also leave the river every half hour, return fare on these 1s. What can I say for Eaton Hall gardens? They are a treat in store for those who have not seen them, and if Liverpool is visited set one day apart for Chester to see the nurseries and one of the finest gardening establishments in the north of England.

In conclusion, I advise all gardeners, when they arrive in Liverpool, to buy Benson's Liverpool Penny Railway Guide, which gives all the local trains, steamers, 'buses, and trams, their starting points and destination, as well as the exact time between each 'bus or tram. Bring also the *Journal of Horticulture* in your pocket, or that portion of it that

contains these notes, and then each will possess two reliable guides.—A CITY MAN.

P.S.—The station given from the Central for Sefton Park at page 482 last week should be St. Michael's and not Mersey Road as stated. St. Michael's is the next station to Otterspool, and should be substituted in the next paragraph for Mersey Road.—A. C. M.

### VIOLETS IN FRAMES.

THERE is no certainty of gathering blooms in autumn, winter, and spring without employing means that protect them from cold and wet, whilst admitting the full influence of light and air. Considering that half the year the plants require full exposure for the growth made and perfected outdoors, the situation should be open. Shelter is essential. A hedge of Privet, Holly, and Yew, about 4 feet high all round, will break the force of wind from whatever quarter; but a clear space must be kept between the hedge and the beds equal in width to the height of the former, as hedges shade even on the sun side, and the Violet plants should be outside the shadow caused by the hedge. Walls are the worst shelter conceivable for Violets, as they stop, not sift air, as hedges do. The site

admixture of the ingredients, and be careful to choose dry weather for the operation. Turfy loam cannot always be had, so that material at command must be utilised. The natural soil being light loam take four parts, add a part pulverised clay, chalk broken small a part, old cowdung a part, and incorporate thoroughly, adding a bushel of soot, and a similar quantity of wood ashes to every thirty of the compost, thoroughly mixing. Heavy soil in four parts should have one part added of lime rubble or burnt clay, a part horse manure or leaf soil, and half a part charred refuse. If deficient of grit, add half a part road scrapings. A bushel of soot may be added to every thirty of the compost. Soils that are of medium texture will only need an addition of a fifth part of thoroughly decayed farmyard manure and some old lime rubble. To all, an addition of half-inch bones may be made, one part to thirty of the compost.

*Forming the Beds.*—Secure the drainage with a thin layer of sods, grass side downwards, and sprinkle with crushed bones or calcined oyster shells, then introduce the compost. It should be put in evenly, and pressed down firmly, but it must be in such a condition as not to clog or adhere to the boots. The soil should be slightly raised in the centre, but not much, and need not be more than 9 inches deep.

*Preparing the Plants.*—Success depends on the length of season the

Fig. 94.—CROXTETH.

should be high and dry. Plants grown on high ground are hardier, the growths more thoroughly solidified than those produced in low sites, where damp gathers soonest and remains longest. If not drained naturally it must be so artificially, so that water cannot lodge within 3 feet of the surface. Drainage insures the free percolation of water through the soil; rain enters it freely, sucking in air and life, adds 2° or 3° to the warmth of the soil, and aids in the preparation of food in an acceptable form for absorption by the roots and concomitant assimilation by the plants.

*Arranging the Beds.*—The ground should be disposed in beds with alleys or pathways between. The ends of the beds are best east and west if they are to be covered with lean-to or three-quarter span frames; and the ends of the beds should be north and south if span-roofed frames are employed. The width of the beds must accord with that of the frames, and the alleys ought not to be less than 3 feet, and need not exceed 4 feet 6 inches in width, even for the widest frames. The first named is suitable for beds of 4 feet wide, and the latter for those of 6 feet in width. If the beds are to be permanent, which is strongly advised, it is a capital plan to form the sides of brickwork, and 6 feet in width from outside to outside of the brickwork, so as to be covered with frames of that width. Where the ground is wet and low raise the beds four courses of bricks above the surrounding ground level.

*Compost.*—Turf yellow loam five parts, the top 3 inches being taken off with its turf in autumn and stacked grass side downwards, will be in good condition by spring; thoroughly decayed manure one part, and old mortar rubbish, removing all pieces of wood, and breaking small so as to pass a sieve with 1-inch mesh. Chop the turf up moderately small, and incorporate the whole together, then add a bushel of soot to every thirty of the compost, and turn over a couple of times so as to insure the thorough

plants have to make a full and free development of the crowns from which the blooms are produced. Unless these are formed in the previous summer blooms will be sought in vain, for, however good the treatment after, they, having no buds, are barren. To wait until May for suckers or runners is too late to get strong plants for flowering in autumn and through the winter. The proper way is to take up old stock that is past flowering and in good health, as sturdy stock only afford vigorous offshoots, and part the plants, singling out and saving all the finest side shoots whether of sucker or runner kind, which, although having no roots at the time, soon make some if pricked out in pans or boxes and stood where they get a gentle moist heat. As soon as this is effected they must have air to prevent weakness and drawing. This is readily accorded in a cold frame, but it must be protected from frost in cold weather, and the atmosphere kept so as to accord with the weather. The suckers or runners may be placed in frames when detached in light soil with a third of leaf soil intermixed as close as they can be put in without crowding, where they can be kept close for a time, shaded from bright sun, and sprinkled or syringed to maintain the leaves in a fresh condition. They should have air freely when root-d, and be gradually hardened until they are fit to plant in the prepared beds. The early part of March is a proper time to put in the suckers or runners, and by the close of April or early in May they will be fit to put out in the beds. When the stock is short suckers or runners may be taken in December and January without lifting the plants, taking them off those in frames and inserting round the sides of pots; root them in gentle moist heat, and afterwards transfer to cooler quarters. Ordinarily a sufficient number of well-rooted suckers can be had from plants that have been covered with frames. Properly hardened off, these are eligible for planting as they will have acquired a tendency to

make and complete an early growth and flower at an earlier season by previous treatment.

Plant in rows 18 inches apart for the strong-growing kinds, and 15 inches asunder in the rows; medium growers 15 inches asunder, and 12 inches apart in the rows; small growers 12 inches apart one way, and 9 inches the other. In prepared beds the plants need not be put on ridges; but the crown should be kept well up to allow for mulching, occupying a kind of knoll. To set plants on the flat and afterwards mulch, so as to bury the crown, is only courting disaster in destroyed centres and multiplicity of side growths and suckers. Firm the soil well about the plants and water at once. The time to plant is from the middle of April to the middle of May, according to the season, but it is better to be a little too late than too early. The chief thing, however, is to have sturdy, well rooted, and hardy plants. Shade for a few days if the weather be sunny until established.

**Summer Treatment.**—Water in dry weather once a week thoroughly, and syringe each evening in hot weather. Mulch with thoroughly decayed manure or leaf soil, and repeat as it becomes reduced. Keep free of weeds and runners, and feed with liquid manure from May.

**Season of Bloom.**—Towards the close of August flowers will appear, and by the middle of September they will be plentiful. From this they will flower right away into spring, or until all the buds in embryo have developed into flowers. Our climate, however, is so variable that a continuous supply cannot be depended on unless steps are taken to exclude frost, excessive moisture, and promote a genial atmosphere. This is effected by lifting the plants and transferring them to frames or pits, or by covering the plants with frames where grown. The latter is much the better, though the other is more general through being more in accordance with our view of the uses to which the frames can be put when not occupied with Violets. It is, indeed, a practice that is convenient, but is bad, as it is performed when the plants have commenced to develop their flowers; and however carefully the lifting is performed there is a great loss of active feeders, and some time must elapse before they are again present in such force as to meet the requirements of the developing blooms. They receive a check, and the rooting powers have not recuperated soon enough to maintain a succession of blooms through the autumn and winter, though it may do so early enough to insure a capital supply of flowers in favourable weather soon after the turn of the days, or in February onward. In that respect lifting has its advantages, albeit the flowers are never so fine as when the plants are allowed to flower with their unimpaired root-action where grown.

**Period of Covering with Frames.**—This must be determined by the weather, but they should be in position by the end of September, so that the lights can be used upon the first setting-in of frost and continued cold and wet weather, as to have bloom in autumn and winter the plants must be kept in steady progressive growth, and this can only be effected by frames that admit of a free circulation of air, full exposure by ready removal of the lights, and means of heating so as to secure in the severest weather a temperature of 45° to 50° by day and to exclude frost at night. The frames will be needed in ordinary seasons from the end of September until the flowering is over in spring.

**Ventilating and Heating.**—Whenever the temperature outside is over 35° air should be admitted. When the outside temperature is 50° the lights should be raised to their fullest extent or removed; but if rain prevail the lights should only be raised so as to admit of a free circulation of air. Heat should be afforded so as to maintain a temperature of 50° by day in mild weather, and 45° in dull and cold weather; at night the temperature may fall to 40° in cold weather. A little warmth in the pipes is of great benefit, even in dull wet weather, in inducing a circulation of air. In very severe weather merely employ fire heat to exclude frost at night, and maintain 40° to 45° in the daytime.

**Winter Treatment.**—In addition to ventilating it will be necessary to look over the plants occasionally for decayed foliage, every particle of which must be removed so soon as it appears, and every defective and small flower, as well as spent ones, should be carefully removed. The mulching should be renewed in autumn, putting on some sweet thoroughly decayed manure or leaf soil after a thorough cleansing of the plant prior to putting on the frames, and if the ground be dry a thorough soaking of water should be given through the mulching, employing a rose watering pot. Whenever the plants become in the least dry a good watering should be given over the foliage, but liquid manure should be poured between the rows, and kept clear of the foliage and flowers.

**Duration of the Plants.**—After flowering the plants should be destroyed and fresh plantations made annually, it being advisable to give a change of soil each year, and occasionally a change of plants will be found beneficial, the changes being best when made from heavy soil to light, and *vice versa*.

#### SELECTION OF VIOLETS FOR FLOWERING IN AUTUMN, WINTER, AND EARLY SPRING.

##### I. Strong growers.

*Victoria Regina*.—Purple, single; the best autumn and winter bloomer.

*White Czar*.—White, single; best white autumn and winter bloomer.

*Odoratissima*.—Bluish violet, single; very fine in early spring.

##### II. Medium growers.

*Neapolitan*.—Double; lavender, white eye; best in spring.

*White Neapolitan*.—Swanley White, Count Brazzi's, &c., double, or semi-double, white; best in early spring.

*New York*.—Double, deep mauve streaked red, with white eye; best autumn and winter bloomer.

*De Parme*.—Double, deep lavender, white eye; best in early spring.

*Marie Louise*.—Double, lavender blue, white eye; best in autumn and winter. This kind is very liable to develop under cultivation into New York—i.e., become deeper coloured, and have red streaks. It is much confounded with that variety.

##### III. Small growers.

*Patrie*.—Double, purple-violet, streaked red; best dark double Violet in cultivation. Very old and very good, blooming from September to April. It is the colour for the "Dark Blues."

*Double Pink*.—Very fine, best in spring; somewhat stronger growing than *Patrie*.

All have long flower stems, large flowers, and great fragrance.—VIOLETA.

#### CHERTSEY AND DISTRICT HORTICULTURAL SOCIETY.

JUNE 17TH.

THIS being a "district" Society, the shows are moveable, being held first in one then in another of the chief centres of population in the locality. This population is not only considerable, but consists of many wealthy families, London merchants and others, who have excellent gardens managed by excellent men. The Exhibition was held this year in Woburn Park, Addlestone, an admirable site kindly placed at the disposal of the Committee by the President of the St. George's College. It was the twenty-first annual Show, and to cite from the "report," "During the twenty-one years of the Society's existence the Committee are encouraged to believe it has done good service for the advancement of floriculture and horticulture in the neighbourhood." There cannot be a doubt that it has done great good, and a very commendable spirit of emulation exists amongst the gardeners of the district, who prove their ability by their work. The Exhibition, to be briefly noticed, was not the largest that has been held, but ranks among the best, not a few of the products being of a superior character. Among the successful competitors were Mr. J. Reeves, gardener to W. Hewett, Esq., Templemere, Oatlands Park; Mr. J. Reed, gardener to E. Petit, Esq., Broadwater; Mr. J. Child, gardener to Mrs. Slade, Claygate, Esher; Mr. J. Plowman, gardener to C. G. Lavers Smith, Esq., Oakfield, Walton; Mr. W. Sutton, gardener to J. S. Sassoon, Esq., Ashley Park, Walton; Mr. Millican, gardener to H. Corbett, Esq., Walton; Mr. Waite, gardener to Col. W. P. Talbot, Glenhurst, Esher; Mr. Sparrow, gardener to Rev. A. Bramwell, Barrow Hills, Chertsey; Mr. Carpenter, gardener to C. J. Abbot, Esq., Rydens, Walton; Mr. Harvey, gardener to Capt. C. F. Terry, Hersham; and Mr. J. Thorne, gardener to A. E. Flood, Esq., Walton.

In the class for six flowering plants Mr. J. Reeves secured the first position with fresh and bright examples of *Clerodendron Balfourianum*, a *Kalosanthes*, *Tabernaemontana*, *Statice*, *Anthurium Scherzerianum*, and a *Rhynchospermum*; Mr. Reed following. Mr. Child was first in the class for four plants with well grown neat specimens—two varieties of *Allamanda*, an *Anthurium* and *Statice*. Mr. Plowman securing second honours. Mr. Child staged by far the best miscellaneous collection of stove and greenhouse plants, including a separate variety of *Cattleya Mossiae*. Mr. Sutton was also awarded a first prize in this class. The prizewinners for fine-foliaged plants, which were very good, were Messrs. Reeves, Sutton, and Reed, the former staging *Phoenix reclinata*, *Caladium Prince Albert Edward*, very fine; *Croton majesticus*, *Cycas revoluta*, a *Cocos* and a *Cyathea*. Ferns were admirably represented, the prizes for six plants going to Messrs. Reed and Reeves; for four to Messrs. Millican and Sparrow. Mr. Millican was first with hardy Ferns, and well won Mr. Rooke's special prize for British species.

Fuchsias were excellently represented, Mr. Reeves being first with six plants, splendidly grown specimens 6 to 8 feet high, the flowering sprays almost hiding the pots. Messrs. Reeves, Plowman, Child, and Reed also showing most creditably. It was pleasing to observe the absence of close lacing in the preparation of these elegant plants, which not unfrequently amounts to distortion. *Caladiums* were wonderfully well grown and very handsome, finer plants being seldom seen than those staged by Mr. Reeves, *bicolor splendens*, *Houletti*, *Meyerbeer* and *Alfred Bleu* being 4 to 5 feet high and the same in diameter. Mr. Child was worthily awarded the chief prize for beautiful fresh pans of *Achimenes*, and Mr. Waite for admirably grown *Gloxinias*, 18 inches in diameter, each with two dozen very large flowers. Messrs. Sparrow, Stedman, and Carpenter also competing well and successfully.

Tuberous *Begonias* were of great excellence, not large but wonderfully vigorous and well flowered. Mr. Child's first-prize plants were from 18 inches to 2 feet in diameter and densely laden with brilliant blooms. Messrs. Thorne, Reeves, and Carpenter had smaller well grown plants in superior varieties. Messrs. Child, Reeves, and Millican were the prize-takers in the *Pelargonium* classes with fresh medium-sized specimens; and Mr. Clay, Kingston-on-Thames, staged a number of seedlings of show varieties which were highly commended. Table plants were staged in large numbers, Messrs. Reeves, Waite, and Reed being the successful exhibitors, and *Jacaranda mimosæfolia*, perhaps the most elegant plant in the collections.

Groups of plants arranged for effect invariably constitute a prominent feature at the Society's shows. G. F. Wilson, Esq., F.R.H.S., gave the first and second prizes for arrangements in a space of 10 by 5 feet. Mr. Reeves was the premier exhibitor with one of the lightest and most tasteful groups we have seen, consisting of *Humeas*, Canadian and Japanese Lilies, *Casuarinas*, *Cocos*, brightened with Tuberous *Begonia*, a telling *Amaryllis*, and *Campanulas*, relieved with several plants of *Saxifraga pyramidalis*, and edged with golden *Selaginellas* and *Panicum*. Mr. Plowman was placed second with plants of good quality but not devoid of "packing," Mr. Millican closely following with a cheerful arrangement, but the front too close and smooth. This group was remarkable as containing *Chrysanthemums* as fresh in foliage and flowers as in November; indeed, better blooms of Golden Middle Marthe have perhaps never been seen than on a plant in this creditable collection. Mr. Sutton was distinctly first in the "large group" class (14 by 7 feet) with a beautiful arrangement, the back

consisting of healthy Palms interspersed with Cauterbury Bells, a central mass of Petunias, and a margin of dwarf Ferns, Caladium argyrætes, and fine Gloxinias, relieved with Liliums and pyramidal Saxifragas. Mr. Harvey was the remaining competitor, and was properly adjudged the second prize.

The display of fruit was limited, and it must suffice to say that Mr. Sparrow was placed first with both black and white Grapes—Foster's Seedling and Black Hamburg; Messrs. Waite and Sutton following. The best Melon in the Show was Hero of Lockinge, exhibited by Mr. Child; the best scarlet flesh being Benham Beauty, staged by Mr. Sparrow. Marguerite was the finest Strawberry, and well won the first prize for Mr. Sharpe of the Royal Strawberry Gardens, near Virginia Water, where all visitors gather and eat what they like for 9d. Mr. Harvey was second with La Grosse Sucre large and highly coloured, and Mr. Child third with James Veitch.

Several stands of Roses were staged in competition for the prizes, the blooms being small but fresh, Messrs. Sparrow, Carpenter, and Waite being the prizewinners; and the same exhibitors, with Messrs. Reeves, Reed, Harvey, Thorne, and Waite, were successful in other classes for cut flowers.

In one of the Pelargonium classes an exhibitor appeared to have forgotten the conditions of "three trusses to form a bunch," for the Judges found nine trusses of one variety neatly tied up, and spread them on the board. This unfortunate accident lost the grower a prize. In the class for drawing-room epergnes Messrs. Millican and Plowman were the successful exhibitors; and in the ladies' class Miss Castle had a charming study in yellow—a basket of Corn Marigolds, Pansies, Roses, Welsh Poppies, and Ferns; it was most deservedly awarded the first prize in its class.

Vegetables were staged in first-rate condition by Mr. Waite, his collection of eight dishes being of the very best quality. Telephone Peas were of surprising excellence so early in the season; Waite's Seedling Tomato, of the Stamfordian type, splendid; and Cauliflowers, Beans, Carrots, Turnips, Potatoes, and Asparaguses of marked excellence. The Show was admirably managed by Mr. T. Rawlings, the experienced and courteous Secretary.

### THE DELL, EGHAM.

IT is a pleasant run of just under an hour from Waterloo to the quiet and unpretentious little town of Egham, which is similar to many that may be found in the rural districts of Surrey, and a still more agreeable journey by road for a distance of about two miles conveys the visitor to Baron Schröder's celebrated garden, The Dell. From Egham there is a steep ascent nearly the whole of the way until Englefield Green is reached; and some charming cottage gardens are passed, embowered in Roses, Honeysuckles, and Fuchsias, everything possessing that fresh bright appearance so characteristic of gardens and vegetation in South Hants or in the neighbourhood of Ventnor in the "garden of England." Partly hidden by trees a glimpse is obtained of the magnificent pile of buildings, the Royal Holloway College, that has been erected at the cost of £300,000, and which, it is said, Her Majesty will shortly open in person as her first public act in her jubilee year. Extensive views of a very pretty landscape can be obtained from here, and on a bright June day of the typical poetical kind we might be disposed to pause a little; but with dark and threatening clouds overhead, and a keen cold wind unpleasantly suggestive of March, we hasten to complete our journey, and soon come in view of the neatly kept symmetrical Holly hedges which form the boundary of The Dell gardens.

This estate, which comprises about 150 acres, is situated on the confines of Windsor Forest, commanding some delightful views in the direction of Windsor Castle. There are really two gardens, one attached to the house having sufficed the original owners; but when Baron Schröder took possession some twenty-two years since it was found to be too limited in its area, and the proximity of the glass houses to the residence was also objectionable. In consequence, a considerable extent of land was procured immediately opposite, but inconveniently separated by a public road. There a new garden was formed; the houses were removed from the old garden, new ranges were erected, an elegant cottage for the gardener, bothies, potting sheds, &c. A kitchen garden was also formed, and the old garden was devoted to choice Conifers, a magnificent collection of Rhododendrons, flower beds, and lawns. An admirably constructed commodious tunnel of white glazed bricks now passes beneath the road from one garden to the other, and with dense Holly hedges on the roadside a visitor would not suppose that he was so near a public thoroughfare. Leading to the house from the road is a curving carriage way, having on each side numbers of Golden Yews, Retinosporas, Biotas, and variegated Hollies in the foreground, with tall Conifers, especially some fine Douglas Firs, behind. A spacious lawn extends in front of the house, near the centre being a grand old Cedar of Lebanon covering a great extent of lawn with its widely spreading branches, and having quite a forest of huge stems like other large old specimens of this stately Conifer. The more slender Cedrus atlantica is represented by several specimens of good size, one being notable for the strongly marked glaucous tint. Then there are scattered specimens of the choicest Retinosporas, which appear in excellent health, the very bright green Cupressus erecta viridis, some luxuriant graceful Deodars, with several Abies, A. Hookeri being especially handsome, Cryptomerias, Golden Yews worked as standards on the green Irish Yews, and numberless others are beautiful examples of well-grown plants.

### RHODODENDRONS.

The great feature of this garden is, however, the Rhododendrons, which are special favourites with Baron Schröder, and after several years' careful selection a collection has been formed that in number of distinct handsome varieties is equalled in few if any private gardens. The beds

are of great size, and so vigorously do the plants grow that they need an occasional thinning on a somewhat liberal scale. They flower most profusely, and though considerably past their best at the time of our visit, some idea could be formed of the brilliant floral display they provided a week or two earlier. The effect is much improved by the care exercised in the arrangement of the plants of particular varieties, so that one colour does not "kill" another, but rather heighten its beauty by suitable contrast. This is an important matter, and it does not always receive the attention it deserves, the principal object being apparently to arrange the plants according to their respective habits. Where Rhododendrons succeed they are invaluable garden shrubs, and one advantage of planting a number of evergreens of this kind is that the garden never has such a dreary appearance in winter as if deciduous shrubs or trees predominate. The soil had to be specially prepared for the Rhododendrons before they were planted, large quantities of good loam and peat being obtained for the purpose; indeed, a large portion of the garden has been renewed or improved by the introduction of fresh soil at considerable expense and labour. The deciduous hardy Azaleas, that constitute an important portion of "American gardens," are also well represented, their bright yellow, orange, red, and variously tinted flowers filling the air with fragrance. Beds of Kalmia latifolia similarly attract attention, and very seldom is this lovely shrub seen in such luxuriance as at The Dell, producing its large clusters of pale pink wax-like flowers by hundreds, which are admirably adapted for cutting and last well in water. There are also beds of hardy Heaths, and other plants of a similar character, together with beds cut in the lawn for flowering plants of the Pelargonium type. Near where the glass houses formerly stood is a remarkable plant of the old double white Camellia japonica, which is the largest we have seen out of doors. It is planted against a wall, but receives no further protection except in the winter, when it is covered by a glass roof. It is about 15 feet high and 30 feet in diameter, the stem being of immense size. The plant is in excellent health and produces its flowers abundantly every season. Attached to the house is a fernery, tastefully planted in the "natural" style, huge pieces of stone and rock being irregularly disposed to form recesses and pockets, in which the Ferns are planted and their fronds droop over gracefully, clothing the house in a refreshing greenery. Within a few yards from this house the garden abuts on Windsor Forest, and from a kind of terrace walk overlooking the "ferny glades" some delightful views are obtained, especially from the dining-room window, which commands a vista three miles in length, bounded on each side by stately Beeches and other trees, and terminated in the distance by the castle towers.

### THE ORCHIDS.

Quitting this garden, we have yet much to see, for the marvellous collection of Orchids has rendered Baron Schröder's name familiar wherever these plants are prized, and under the care of the genial gardener, Mr. Ballantine, The Dell Orchids have taken a prominent place amongst the best-grown specimens in this country. There is a very general impression that in gardens noted for specialties it must be expected that some other departments are proportionately neglected, but one of the best examples to the contrary is afforded in the garden under notice, for it there seems as if a specialty is made of everything taken in hand. It is true that the skill of the gardener is substantially supported by the employer's liberality and encouraged by his enthusiastic interest, and in these facts we find the secret of the success, a combination that ought to prevail more generally. In forming collections of Orchids the object is usually to procure as large a number of species and varieties as possible, or to obtain extensive stocks of the most ornamental and handsome forms, but The Dell collection has not been formed exactly upon either of these plans. Of many cultivated Orchids the varieties are now very numerous, and amongst these some are imported at times greatly superior to the ordinary forms or the typical species; these invariably realise high prices, and their value is not so liable to fluctuate as that of species which may be scarce one week and the sale-rooms be filled with imported plants the next. When an extra fine variety of any kind is found it is rare that more than one plant is obtained, and as the increase by division is a slow one, it must always remain scarce. Similar remarks apply to most of the hybrids raised in this country, and it is to these and the choicest introduced varieties obtainable that Baron Schröder has given his special attention, with the result that his collection is richer in such varieties than any other amateur's. Next, the object has been to grow all the plants in the best possible manner, and how well this has been accomplished all who have visited The Dell will readily admit. The houses are well constructed, spacious, light, with ample means of ventilation, shading, &c., and filled with every convenience to assist the cultivator, but beyond this the plants need the careful attendance of experienced hands, and in this work Mr. Ballantine receives the aid of a willing staff of assistants. To all, the condition of the plants throughout is most creditable; an unhealthy specimen is not tolerated, and insects are as scarce as anyone could wish them to be.

To refer to the Orchids in detail would occupy more space than can be spared, and we must confine our attention to the principal of those in flower. First, of the Cattleyas there is a fine display, the magnificent C. gigas and C. Sanderiana being wonderfully fine; one of the former from Mr. Day's collection, and one of the latter with lips 3 inches in diameter, are grandly coloured varieties with numerous large flowers. Of the lovely C. Wagneri, a plant in a basket has eight fine flowers, the white sepals and petals contrasting well with the rich orange lip. Cattleya Mendeli is represented by some choice varieties, one having a very rich crimson lip beautifully fringed, and another named superbum being remarkable for its handsome form. The useful C. Warneri, C. Mossii,

and fragrant golden *C. citrina* are flowering well; vigorous specimens of *C. Gaskelliana*, *C. Percivaliana*, *C. Calummata*, and the recently certificated *C. Reineckiana* with broad white petals and petals and a gold and purple-fringed lip also add to the attractions of the house. An exceedingly beautiful specimen of *C. Skinneri alba* is grown in this house and has seventeen racemes of about six flowers each, but it is now past its best and the flowers have been removed, for one point strictly observed is never to allow the plants to weaken themselves by bearing flowers too long, and plants of very choice varieties that are not very strong are not permitted to flower for a season or two. *Lælia purpurata*, and especially that grand variety *Williamsi*, is in superb condition, plants bearing four or more racemes and four to six flowers each, most richly coloured. The rare and valuable *Lælia Canbamiana*, a hybrid between the popular *Lælia purpurata* and *Cattleya Mossiæ*, has two fine racemes of three flowers each. The superb varieties of *Lælia anceps*, of which flowers were shown some time ago at South Kensington, are growing in this house, but, of course, not flowering now. Some healthy *Pleiones* are suspended from the roof, and of other plants the choice *Lælia bella* and *Sobraia xantholeuca* are particularly remarkable.

The Bladderworts, *Utricularia montana* and *U. Endresi*, the former with white flowers blotched with yellow in the centre, the others pale lilac or mauve, are grown in the *Cattleya* house, and thrive extremely well, plants in baskets 6 inches square having twenty to thirty spikes each, their principal requirement being an abundant supply of water. Passing these, several *Vandas*, including *V. teres Andersoni*, a large-flowered variety, *V. Marriottiana*, and *V. Sanderiana*, a grand variety, with a raceme of eight large flowers, the plant having five leads, we come to several *Dendrobiums*, the white *D. Deari* flowering very freely, in some cases with as many as eleven flowers in a raceme. This will be a useful *Dendrobe*, as the flowers last well both on the plant and when cut and placed in water. A dark-coloured *D. Bensoniæ*, and the large *D. Falconeri giganteum*, both fine varieties, together with the seldom seen *D. MacCarthiae*, a lovely species with drooping flowers, with long pale purple sepals, petals, and lip. A huge *Anthurium Andreanum* stands at the end of the central bed in this house reaching to the roof, and bearing twenty-six bright scarlet spathes, some 8 inches long and 6½ inches broad; it is the finest plant and variety we have seen. Near to this is a bank of *Cypripediums*, which include some valuable varieties and hybrids. One of the first noticed was the Garbrand Hall specimen of *C. Stonei*, which Mr. Child has so frequently shown at the leading exhibitions; then the choice variety of that species, *C. Stonei platytanum*, an exceedingly scarce plant, is observed, three healthy pieces growing well, but not now in flower. *C. Lawrencianum*, *C. superbiens*, *C. selligerum*, *C. Godefroyæ*, *C. Leeannum superbum*, *C. lævigatum*, and *C. vexillarium* are all in first-rate condition. A strong example of *C. grande* is similarly fine, and near it is the valuable *C. Morganæ*, a most vigorous plant, probably the largest in cultivation.

A house is devoted chiefly to fine masses of *Cœlogyne cristata* and its best varieties, some 3 feet square. Adjoining this is a *Nepenthes* house, and then we pass into the cool Orchid house, which is extremely gay now. *Odontoglossum vexillarium* is well grown, plants in 6 and 8-inch pots having twelve to twenty racemes each, some of the flowers 4 inches across the lip and others very richly coloured. *Dendrobium infundibulum* and *D. Jamesianum* are flowering well, plants of the latter having twenty-three large flowers each. *Odontoglossum Halli* and *O. crispum* are represented by large plants and fine varieties, but one of the most remarkable specimens is an *Oncidium macranthum* with five racemes, bearing a total of 141 flowers. The plant is placed in the centre of the bed, and the racemes are trained to each end. Numerous *Masdevallias* of the *Harryana* and *Veitchi* types impart much rich colouring to the display, and several curiosities like *M. Trochilus* and *M. Winniana* are included. In another small house are grown the choice *Odontoglossums* that have obtained such remarkably high prices—namely, *Knox's* variety of *O. crispum*, *O. crispum apiatum*, *O. Sanderianum*, *O. Veitchi* (mirabile), *O. Pescatorei*, *Veitchi*, and *Schrœderianum*, *O. Ballantinum*, and others which are well known as the most beautiful forms yet obtained. In other houses and pits *Calanthes*, *Phalenopsis*, *Cymbidiums*, *Vandas*, *Odontoglossum vexillarium*, and innumerable others are grown, but these notes are assuming such a formidable length that they can only be incidentally mentioned.

#### FRUIT AND PLANT HOUSES.

As already intimated, the Orchids do not engross the whole of the gardener's attention, and the fruit houses form an important department. There are two ranges of vineries, each about 100 feet long, the vines bearing excellent crops of fruit, the earliest having been fit for table since Easter. Then there are Plum and Peach cases covering a wall 300 feet long, and comprising healthy trees of all the best varieties, from which crops of fine fruit have been obtained for several years. Pits are devoted to Melons, Cucumbers, Pine Apples, *Amaryllises*, Strawberries, Gardenias, and Ferns. A flower house is gay with Tuberous Begonias, Carnations, *Petunias*, *Gladiolus*, *Spiræas*, *Pelargoniums*, and Roses, and a stove contains, amongst a general collection, the grandest specimen of *Anthurium Veitchi* we have seen, having about thirty leaves, the blade 4 to 5 feet long. Concerning these and the well-kept kitchen garden much might be written, and to all equal praise must be accorded, for no visitor can leave The Dell without the feeling that he has inspected a really model garden.

#### THE NORTON PANSY CLUB.

KING'S NORTON and King's Heath, together with the Moseley district, forms one of the outskirts of Birmingham, away out of the smoke of the

town, and a district where gardening pursuits can be followed with considerable pleasure. A few amateurs interested in the Pansy resolved upon forming a small Society for the purpose of further developing a taste for Pansies and Violas in the locality of Birmingham, and the first Exhibition of the new Society was held in the King's Heath Institute, a very suitable place for such an Exhibition. Being a very recently formed Society the local exhibitors were but few, but some excellent blooms were staged, and there appears to be a determination amongst the members to make a much larger exhibition last year. In the amateur classes Mr. James Sinkins, both for eighteen and twelve blooms, with very fine flowers; My Lady, William Cuthbertson, Mr. T. McComb, Grace Rudgard, and Miss Orkney, being the most striking in these stands. Mr. A. Hunt was second for twelve blooms, Miss Reeve, Charles Stansell, and May Tate being very fine. Mr. T. A. Eaves was placed third. For six Fancy Pansies Mr. C. E. Scarse was first with a nice lot, which included a very fine bloom of Major Skrimme. Mr. John Innes was second, his blooms of Charles Stansell, May Tate, and Evelyn Bruce, very good.

In the open classes Mr. I. H. Patterson was first for twelve, also for six Fancy Pansies, his finest blooms being Mrs. E. H. Wood, Lightning, and Mrs. Jameson. For twenty-four blooms Mr. Hughes set a very fine stand, and was placed first, Catherine Agnes, Mrs. J. P. Frame, Charles Stansell, Evelyn Bruce, and a seedling Ingomar, an R. K. Mitchell style of flower, and of great quality. There were only two exhibitors of Pansies in pots, just ordinary plants not long since potted. The exhibitors have much to learn in the culture of Pansies in pots.

Messrs. R. P. Laird & Sons, Edinburgh, sent about 100 superb blooms of Fancy Pansies, not for competition, the flowers being remarkably fine in every respect and rich in colouring. Princess Beatrice, Evelyn Bruce, Campbell-Bannerman, Duke of Grafton, Mrs. Duncan, William Dick, Pilrig, Mrs. J. Downie, Alfred Mitchell, and James Gardiner were amongst the most striking; also a wonderfully fine bloom of William Dean, which was singled out as one of the finest flowers in the exhibition. May Tate was extensively exhibited throughout the Exhibition, but varied in its marking of the top petals.

Mr. John Forbes, florist, Hawick, sent, also not for competition, a very fine lot of quite 150 blooms of Fancy Pansies, including two grand seedlings not named, 36/85 and 95/85. His blooms throughout were fine, especially George Innes, Miss Neeve, Bob Montgomery, Mrs. McIntosh, William Dean, Pilrig, G. O. Trevelyan, and Lord Rosslyn. Violas had but one exhibitor for competition in Mr. Cooper, gardener to the Right Hon. Joseph Chamberlain, M.P. Mr. Wm. Dean, Walsall, staged a very fine collection, not for competition. Mr. Chamberlain's residence, Highbury, is close to King's Heath, where the exhibition was held, and Orchids and stove and greenhouse plants were sent by Mr. Cooper; and Messrs. Pope & Son, nurserymen, contributed a handsome group of Orchids and other plants, including a fine specimen of the finest of all the Golden Tricolor *Pelargoniums*, Mrs. Henry Cox, and a lot of extremely fine Fancy Pansy blooms. Mr. Hans Niemand contributed a beautiful group of plants, including *Hydrangea paniculata grandiflora*, with immense heads of flower; *Nephrolepis Baueri*, *Onychium auratum*, a lovely Fern, and the new *Adiantum rodophyllum*. Mr. R. H. Vertegans contributed a good collection of cut herbaceous and alpine plants.

#### ROYAL HORTICULTURAL SOCIETY.

JUNE 22ND.

HARDY flowers were remarkably abundant at this Exhibition, and the conservatory had a particularly gay appearance. Roses, *Pelargoniums*, and miscellaneous contributions all added to the extent and beauty of the Show, which was one of the most interesting held at South Kensington this season.

Classes were specially provided for *Pelargoniums* and Roses, but although the prizes were good they did not bring many competitors, and the greatest portion of the Show was composed of the miscellaneous groups not in competition. Messrs. Paul & Son, Cheshunt, were the premier exhibitors of Roses in pots, securing the first prize for thirty plants, standards and dwarfs, in capital condition; Mr. W. Rumsey, Waltham, following with smaller plants, all dwarfs. For cut Roses Mr. G. Prince, Oxford, took the lead with twenty-four superb blooms, mostly Tea varieties; Messrs. Paul and Son and W. Rumsey securing the second and third places with mixed collections of Teas and Hybrid Perpetuals, but the latter predominated. Show, decorative, and fancy *Pelargoniums* were well represented in a collection from Mr. C. Turner, Slough, for which the first prize was awarded, but Zonal varieties were not of remarkable merit, those from Mr. H. Little being much the best. Cut blooms of *Pelargoniums* were shown by Major Scott, Wray Park, Reigate (gardener Mr. Morgan), and Mr. E. M. Nelson, very bright samples of good varieties, the first and second prizes being awarded to the exhibitors in the order named.

Miscellaneous groups were especially numerous, and alone would have constituted a beautiful exhibition. Messrs. Kelway & Son, Langport, had extensive collections of choice *Pæonies*, *Pyrethrums*, double and single, *Gaillardias*, and hardy flowers. The *Pæonies* were particularly beautiful, three being selected for certificates, and a silver-gilt Banksian medal was awarded for the group, which was one of the best the firm has shown this season. Mr. T. S. Ware, Tottenham, had a magnificent display of *Irises*, *Ixias*, *Lilies*, *Pyrethrums*, *Pæonies*, and hardy flowers. Very handsome were the rose-and-white blooms of *Cypripedium spectabile*, the deep blue *Iris siberica orientalis*, the rich scarlet *Papaver orientale*, and floriferous blue *Polemonium Richardsoni* (silver-gilt Banksian medal). Messrs. Barr & Son, Covent Garden, obtained a silver medal for groups of single and double *Pyrethrums*, *Pæonies*, English and Spanish *Irises*, double *Ranunculuses*, Foxgloves, and many other handsome flowers. Messrs. Paul and Son, Cheshunt, were awarded a silver-gilt Banksian medal for a large and varied collection of hardy flowers, which contained a number of choice species of herbaceous plants as well as specimens of ornamental shrubs. R. J. Measures, Esq., Camberwell Lodge, Flodden Road, Camberwell New Road, S.E. exhibited a handsome group of Orchids tastefully arranged with Ferns, and the silver-gilt medal awarded was well merited. The plants were of moderate size, comprising *Cattleyas*, *Masdevallias*, *Dendrobiums*, *Epidendrum vitellinum*, *Ionopsis paniculata*, *Cypripediums*

and many others of good varieties, and bearing abundance of flowers. A silver medal was awarded to Messrs. W. Paul & Son, Waltham Cross, for an interesting group of ornamental hardy shrubs and trees, including the golden Quercus Concordia, the golden variegated Chestnut, the Purple Oak, Quercus purpurea, the dark purple Prunus Pissardi, the Purple Hazel, several good early Clematises, and a choice collection of lovely Scotch Roses, together with the bright yellow Austrian Briar, Harrisoni, and the orange red Austrian Copper.

Bronze medals were awarded to the following:—Mr. G. Prince, Oxford, for some charmingly fresh Tea Roses; Messrs. Hooper & Co., Covent Garden, for Petunias, and a tasteful group of Gloxinias and Ferns; Messrs. E. H. Krelage & Son, Haarlem, for a superb collection of Pæonies, most varied in colours; Major Lendy for a handsome specimen of Cattleya Mossiæ, about 4 feet in diameter, and covered with flowers; and to John Henshaw, Esq., Harpenden Schools, Herts, for six collections of hardy flowers from boys at those schools. They were tastefully set up, accurately named, and comprised some rare species.

FRUIT COMMITTEE.—Present—Harrison Weir, Esq., in the chair; and Messrs. W. Warren, T. J. Saltmarsh, G. T. Miles, G. Norman, John E. Lane, Arthur W. Sutton, Phillip Crowley, T. B. Haywood, F. Rutland, W. Denning, T. Francis Rivers, J. Burnett, G. Bunyard, R. D. Blackmore, John Woodbridge, and Dr. Robert Hogg.

The exhibits before this Committee were not very numerous nor of remarkable merit. Mr. Lockie, gardener, Oakley Court Gardens, Windsor, sent fruit of Melon Oakley Court, a cross between Dr. Hogg and Egyptian Green-flesh, a green-flesh variety of excellent flavour, which has been shown on several occasions in good condition. Messrs. J. Carter & Co., High Holborn, exhibited samples of Knickerbocker Radish, which had been grown from seed sown in the Chiswick Garden on May 12th; they were not of unusual size, and were passed. Mr. C. J. Jarman, Chard, Somerset, sent a seedling Apple of no special merit. Messrs. J. Veitch & Sons, Chelsea, showed a plant of Fig Pingo de Mel, which was thought to be Angelique. Sir Samuel Davenport, Australian Commissioner, exhibited fruits of Chinese Quince, a variety of Cydonia japonica, with oval yellow fruits about 6 inches long and 4 in diameter, with a firm astringent flesh.

FLORAL COMMITTEE.—Present—James O'Brien, Esq., in the chair; and Messrs. J. Douglas, E. Hill, H. Turner, J. Hudson, R. Dean, S. Hibberd, H. J. Lendy, H. M. Pollett, J. Dominy, C. Noble, H. Herbst, W. Wilks, J. Walker, W. Bealby, H. Cannell, Dr. M. T. Masters, W. Holmes, H. Ballantine, H. Bennett, and G. Paul.

From the Royal Gardens, Kew, were exhibited plants of the beautiful Ceylon Gentian, Exscum macranthum, a biennial introduced in 1853. The flowers are a bright purplish blue with bright yellow anthers. They are borne at the tips of the branches and last for several weeks. From the same gardens came plants of Streptocarpus Dunni, a new plant found at Spitzloop Transvaal Goldfields at from 3000 to 6000 feet elevation. Seeds were sent to Kew by E. J. Dunn, Esq., in November, 1884. The leaves are 2½ feet by 1½ foot across, of a curious greyish green colour, and puckered on the surface. The flowers are tubular, of a dull reddish colour, and are produced most abundantly. Votes of thanks were awarded for these plants, and the information recorded on the labels was very useful, and the practice might be imitated more generally by giving some particulars concerning the origin of plants exhibited. W. E. Hubbard, Esq., Leonardslee (gardener, Mr. S. Ford) showed a plant of Protea named Hubbardi provisionally. It had thick oval smooth leaves, and a terminal head of flowers 8 or 9 inches in diameter, and surrounded by tapering silvery red bracts. Some members of the Floral Committee objected to the name, and thought the plant was an old one, but it was not determined. Messrs. Sander & Co., St. Albans, showed a plant of Odontoglossum chiriquensis, with bright brown flowers, the sepals and petals undulated on the margin, the lip yellow at the apical half. They also showed a plant of Zygopetalum obtusatum growing on a Tree Fern, the leaves narrow and grass-like, the flowers like a small Z. maxillare. Dr. Duke, The Glen, Lewisham (gardener, Mr. Noakes), showed a variety of Odontoglossum vexillarium named guttatum, the lip curiously dotted with white. Mr. Bleu, Avenue d'Italie, Paris, had a Cypripedium, apparently javanicum superbiens, much like the species bearing the latter name. John A. Whittard, Esq., Streatham Hill (gardener, Mr. H. Wright), sent a magnificent specimen of Gymnogramma schizophylla gloriosa. Mr. T. Chnrch, St. Margaret's, Twickenham, had a basket of Ivy-leaved Pelargonium blooms, bright and pretty. A vote of thanks was accorded to Sir Trevor Lawrence, Bart., M.P., Burford Lodge, Dorking, for extremely handsome pitchers of Nepenthes Mastersi and large flowers of Cattleya Wagneri very pure in colour.

Mr. J. Douglas, gardener to F. Whitbourn, Esq., Great Gearies, showed flowers of Lælia majalis, very large and of good colour, for which a cultural commendation was awarded. Mr. Douglas grows the plant in a sunny position, where the plant has a thorough ripening. Mr. R. Dean, Ealing, had a box of single striped Petunias, gathered in the open ground. M. Godefroy Lebœuf, Argenteuil, Paris, sent a Begonia named Arthur Mallet, a hybrid from B. sub-peltata and B. Rex, with bright reddish leaves and dark green veins. Mr. J. H. Beach, Sevenoaks, sent a white Gloxinia named compacta, very dwarf and free. E. B. Foster, Esq., Clewer Manor, Windsor, exhibited a plant of Pelargonium corinna with large well-formed flowers, the upper petals dark crimson and the lower pink. Mr. W. Stacey, Dunmow, exhibited four dozen trusses of Verbenas, representing the beautiful varieties which has been obtained by this raiser. A vote of thanks was accorded for the collection. H. Little, Esq., Twickenham (gardener, Mr. Hill), exhibited a fine variety of Lælia purpurata with large dark-coloured lips. Mr. R. Owen, Maidenhead, exhibited stands of Ivy-leaved Pelargoniums, comprising some beautiful varieties, for which a vote of thanks was accorded. Plants and flowers of Chrysanthemum segetum Cloth of Gold were also sent.

#### CERTIFICATED PLANTS.

*Thunia Veitchiana* (Messrs. J. Veitch & Son).—A hybrid between T. Marshalli and T. Bensoniæ, which has been previously certificated at the Regent's Park. The sepals and petals are narrow, white faintly tinged with purple, the lip veined pale crimson, with numerous yellow filaments in the centre.

*Doronicum draytonensis* (Paul & Son).—A variety with large flower heads 3 inches in diameter, the florets narrow and bright golden yellow.

*Thuiopsis borealis lutea* (W. C. Slocock, Woking).—A compact habited variety, the shoots tipped with bright yellow.

*Petunia Empress* (Hooper & Co.).—A handsome double variety with fine freely produced bright rose flowers. An excellent variety for decorative purposes.

*Double Pæonies* (Kelway & Son).—*Queen Victoria*, pale blush, very full and compact. *Princess of Wales*, large, open, bluish, broad petals. *Princess Beatrice*, a pretty variety with pink outer guard petals, and a dense pink and white centre.

*Cattleya Mossiæ Arnoldiana* (C. Hill, Esq.).—A white variety with well formed flowers, the lip stained with crimson.

*Odontoglossum vexillarium purpureo-radiatum* (Baron Schröder).—A variety with fine flowers, the lip marked with radiating crimson lines.

*Begonia Arthur Mallet* (Godefroy-Lebœuf).—A pretty foliage variety from B. sub-peltata and B. Rex, the leaves of a deep rosy red and veined with dark green, not unlike some of the Bertolonias.

SPECIAL PRIZES.—Messrs. Sutton & Sons, Reading, offered prizes for Melons, two of which were won by Mr. T. Lockie, gardener to the Hon. G. O. Fitzgerald, Oakley Court Gardens, Windsor, with Sutton's Imperial, very fine; and by Mr. Ward, gardener to the Earl of Radnor, Longford Castle, Salisbury, with Hero of Lockinge, neat and well netted. Messrs. J. Carter & Co., High Holborn, also offered prizes for Blenheim Orange Melon, which were won by Messrs. Lockie and Ward with good fruits, and their prizes for Model Cucumbers were adjudged to Mr. Lockie, Mr. Phillips, The Deodars, Meopham, and Mr. J. Bolton, gardener to W. Spottiswood, Esq., Combo Bank, Sevenoaks in the order named.

#### SCIENTIFIC COMMITTEE.

Dr. M. T. Masters in the chair.

*Phycomyces splendens*.—Mr. W. G. Smith reported on the specimen sent to the last meeting by Mr. Wills, and found that *Mucor mucedo* was growing on decayed parts of it; that it produced enormous sporiferous sacs containing 3000 spores; they were five times greater than those of *M. mucedo*, and the supporting stems were 4 inches high. It is a very rare fungus as far as is known at present.

*Peronospora arborescens* on *Papaver dubium*.—He exhibited specimens in which this fungus had attacked the peduncles, completely stripping off the epidermis in many places, and causing the stalks to be spirally or otherwise twisted with remarkable contortions.

*Coniferous Seedlings attacked by Fungi*.—The following communication was read from Mr. Braca, near Salbris, Loir et Cher, France:—

"The few Pine seedlings forwarded to the Scientific Committee are of this season's showing, and are attacked by a virulent form of fungus. I would feel greatly obliged if you could kindly aid in identifying the fungus, and give me any information as to the cause of its appearance, &c. I attribute it chiefly to the unusually cold and wet season that we have had. It has been felt most severely in the seeds of *P. Laricio*, in which I have lost fully 25 per cent.; but it attacks also *P. sylvestris* and *P. austriaca* as well. At present it seems to be dying out, but I am still in great fear of its breaking out again. Now that a little dry weather has set in I am about to try the effect of flowers of sulphur out of a sulphurator, as the only remedy that I can think of as likely to succeed. A plant that is visibly attacked seldom shows signs of life after the third or fourth day. It does not attack transplanted seedlings. My partner, Mr. David Cannon, forwarded samples both to Paris and Versailles for identification, but it seems to be hitherto unknown."

Mr. Smith had examined the seedlings, and found the cotyledons and radicles thoroughly infested with fungus, which was bursting through the surface. The parasite had, no doubt, been derived from the parent tree when in fruit. The following were the fungi:—On Larch seedlings *Cœoma Laricis*; on *Pinus sylvestris* *C. pinitorquum*; and on *Pinus Picea* *C. Abietis pectinata*.

*Morchella crassipes*.—Mr. Boulger mentioned his discovering a fine specimen of this fungus, 1 foot in diameter, near Maidstone, in the museum of which it has been preserved. It was new to Kent, though had been found in Kew Gardens and several other places.

*Humea elegans* with *Peronospora leptosperma*.—Mr. Murray alluded to specimens of *Humea* sent to him for examination, and found that their decay and death was apparently due to that fungus.

*Illustrations of Monstrous Orchids*.—Mr. T. G. Hansen exhibited some beautifully executed drawings of *Phajus grandifolius*, *Odontoglossum crispum*, &c., showing variations in the structure of the flowers, mostly with three labella. The extra ones appeared to occupy the position of arrested stamens. In some the labellum was arrested, but two supplementary and apparently more or less rudimentary stamens occurred. A vote of thanks was given to Mr. Hansen for his communication.

*Eucalyptus globulus* Injured by Frost.—Mr. Smee inquired as to the experience of others upon the injury received by species of *Eucalyptus* during the late prolonged winter. He remarked that all his had perished excepting four trees. One of them was in a pot which had been completely frozen through. A second had been in a dry situation, but all that were planted in moist ground had perished. He noticed that those which were breaking again bore leaves similar to young ones, though they had previously produced the scimitar-shaped leaves. Mr. Lynch remarked that specimens of *E. Gunnii* were injured at Cambridge more this year from the prolonged period of cold than in previous winters with lower temperature.

*Plants Exhibited*.—Mr. Lynch brought the following plants from the Botanic Gardens, Cambridge:—*Pterocarya caucasica*. This derives an advantage from having more than the usually single axillary bud. There are two or three supra-axillary buds to each node, and the first shoots that grew this year were killed by the frost. Another bud, between the leaf-scar and the dead shoot, then arose from each node, and has developed to take the place of the one killed. *Helicodiceros muscivorus* (*Arum crinitum*). This plant had caught a great number of flies, which had perished round the base of the spathe without letting them go again. It "resembles *Arum maculatum*, but attracts carrion flies by means of its strong odour of putrid flesh. The smaller visitors are held fast by sticky hairs in the floral chamber and digested" (Müller, D'Arcy Thompson's translation, p. 564). The hairs in the tube did not appear to dry up as in *A. maculatum*, perhaps in consequence of this being a moist climate, so that the flies could not

escape to fertilise other plants. *Rhododendron myrtifolium* (ponticum var.) from Gibraltar. This is an uncommon and distinct form, with very compact small trusses of bright pink flowers. *Rosa punicea* (R. lutea var.), S. France, and Austria, of a fine colour. *Pyrethrum tenacitfolium*. This is a rare plant and very pretty. *Gunnera manicata*, showing a remarkably fine inflorescence; *Dianthus*, hybr. between *D. barbatus* and *D. alpinus*, *Linaria anticaria*—the flowers exhibit a beautiful system of lines; *Primula Parryi*, and *Hedysarum multijugum*.

*Protea sp.*—A very fine plant with a terminal inflorescence was exhibited by Mr. Hubbard, of Leonardslee. The specific name was undetermined.

*Zygopetalum obtusatum*.—Received from Messrs. Sander, of St. Albans. Mr. O'Brien observed that this was a rare Orchid, and formed the original type species of the "section" ending with *Z. Gautieri*. It is a native of Brazil. A botanical certificate was awarded for it.

*Azalea occidentalis* (?).—Fine sprays were received from Mr. Anthony Waterer, who obtained it from Professor Sargent. It appeared doubtful whether it was a true species or not. Professor MacOwan, who was present, remarked that species occurred in the Columbia Valley, but appeared to be different from the specimen in question. He kindly undertook to examine it.

*Chionanthus virginicus*.—Specimen of flowering shoots from this hardy shrub from North America were received from Mr. Waterer. Dr. Masters remarked upon this as one of the several Japanese "representatives" to be found on the eastern side of North America.

### ROYAL METEOROLOGICAL SOCIETY.

THE concluding meeting of this Society for the present session was held on Wednesday evening, the 16th inst., at the Institution of Civil Engineers, 25, Great George Street, Mr. W. Ellis, F.R.A.S., President, in the chair. The Rev. J. R. Boyle and Mr. H. B. de la Poer Wall, M.A., were elected Fellows of the Society.

The following papers were read:—1, "Note on a Sudden Squall, January 13th, 1886," by Mr. R. H. Scott, F.R.S. This is an account of a remarkably sudden squall of about ten minutes' duration which passed over the south of England on the morning of January 13th. It was first recorded at Falmouth at 8.20 A.M. and passed over London at 10.40 A.M.

2, "The Floods of May, 1886," by Mr. F. Gaster, F.R.Met.Soc., and Mr. W. Marriott, F.R.Met.Soc. The month of May, 1886, will long be remembered for the heavy rains that occurred between the 11th and 13th, and the floods they produced over the greater part of the west and midland counties of England. In fact at Worcester the flood was higher than any that have occurred there since 1770. On the 11th and 12th heavy rain fell over the east of Ireland, there being over 3 inches during these two days at several places in Counties Down, Dublin, and Wexford; the greatest reported being 3.52 inches at Kilkeel, County Down. Over the other parts of the United Kingdom the rainfall on the 11th was under 1 inch. Rain, however, commenced falling about noon on Tuesday over the midland counties, and continued with increasing intensity till Friday morning; the duration at most places being about sixty hours. The heaviest rainfall occurred in Shropshire, where over 6 inches fell at several stations, while at Burwarton as much as 7.09 inches was recorded; the amounts for each day being—0.60 inches on the 11th, 3.10 inches on the 12th, and 3.39 inches on the 13th. Very serious floods followed these heavy rains. At Shrewsbury the extreme height of the flood on the Severn was 16 feet, and at Worcester 17 feet 1 inch above the average summer level. At Ross the flood on the Wye was 14 feet; at Nottingham the rise of the water in the Trent was 12½ feet; at Rotherham the flood was 8 feet 5 inches; and in north-east Yorkshire the Derwent rose to nearly 11 feet above summer level. These floods caused great damage to property and loss of life, bridges were washed away, railway traffic suspended, and thousands of workmen thrown idle. In several places the waterworks were flooded and the towns' water supply was consequently cut off. Mr. Gaster drew attention to the complex character of pressure distribution during the time referred to, and showed how the region of maximum rainfall followed certain of the shallow depressions which appeared over the British Islands. He drew attention to the peculiarities of this type of depression, showing how in many, if not in most cases, the rainfall was heaviest in their rear, and was brought by the easterly, not by the westerly wind. He also referred to some previous instances of heavy floods, in which similar atmospheric conditions prevailed, and explained how it was that as the disturbance passed off snow fell instead of rain, this in its turn being followed by severe cold and in some places frost.

3, "On Atmospheric Pressure and its Effect on the Tidal Wave," by Captain W. N. Greenwood, F.R.Met.Soc. The object of this paper is to show how a little knowledge of weather forecasting, with some practical knowledge of local weather changes, and a good barometer will go far towards forming a right correction for application to the predicted height of the tide, and also to determine what that correction should be in its relation to the fluctuations of the barometer and the prevailing gradient.

4, "Meteorological Results at Levuka and Suva, 1875-1885, with Notes on the Climate of Fiji," by Mr. J. W. Vaughan, F.R.Met.Soc. The climate of Fiji is remarkably healthy. Diseases such as fevers of an aggravated and malarious character, cholera, and liver complaints are unknown.

### HOW ODONTOGLOSSUMS ARE COLLECTED.

ALTHOUGH the geographical range of *Odontoglossum crispum* is comparatively limited, there is a marked difference in the varieties found in various localities. The Pacho Mountains is the home of the finest forms, and here the plants grow on the lower branches of the forest trees in company with *O. gloriosum* and *O. Lindleyanum*, two inferior species in point of beauty, but which have, perhaps, in a great measure been instrumental in producing the beautiful narrow-petaled supposed hybrids, such as *Andersonianum*, *Ruckerianum*, *Jenningsianum*, and others. It is peculiar that, whereas the starry-flowered forms, similar to *Lindley's* type specimen, abound exclusively on the north of Bogota, the woods on the

south, about ten days' journey distant, are rich in the fine round-flowered varieties. Although this Orchid is imported in larger numbers than any other from South America, the risks and expenses are not slight even now. In our case we purchase the exclusive right to collect plants in the woods in certain districts; natives are employed to gather them, for which purpose parties of from four to eight go into the woods, returning in about a fortnight with the result of their labours. After the plants have been cleaned and prepared, and kept on wooden stages for several weeks, they are ready for packing.

They are then fastened to stout sticks, and these are fixed in wooden boxes, so as to leave air space around them. The cases are carried on mule-back to Bogota, a journey of about ten days, and here they are received by an agent, who sends them by mules to Honda, which is reached in another six days. This place is situated on the River Magdalena, and here the cases are put on board a river steamer, which takes them to the seaport town of Savanilla, a journey occupying about five days. Owing to the intense heat on the river journey the plants often perish. The cases then come, as a rule, by mail steamer, *via* Colon and St. Thomas, to England, the passage being made in about twenty-seven days. The risks, therefore, of importing this Orchid are great, and owing to the peculiarly soft nature of the plants they are so liable to decay that in some instances seven-eighths of the consignment are dead on arrival here. The havoc made in the native forests, too, must be considerable, for we calculate that for every three plants actually established in European gardens a tree has been felled.—(*Reichenbachia*.)

### ROSE AND HORTICULTURAL SHOW FIXTURES, JUNE AND JULY, 1886.

THE following are the dates of the principal Shows to be held during June and July this year. The great event of the season will be the provincial Show of the Royal Horticultural Society at Liverpool next week.

York Floral Fête, June 23rd to 25th.

Royal Horticultural Society Provincial Show at Liverpool, June 29th to July 5th.

Bagshot and Windlesham Rose Society, at Bagshot, Tuesday, June 29th.

Canterbury and Kent Rose Society, at Canterbury, Tuesday, June 29th.

Diss Horticultural Society's Rose Show, June 30th.

Royal Botanic Society's Evening Fête, June 30th.

Farningham Rose and Horticultural Society, at Farningham, Wednesday, June 30th.

Croydon Horticultural Society, at Croydon, Wednesday, June 30th.

Reigate Rose Association, at Reigate, Thursday, July 1st.

Tunbridge Wells Horticultural Society, at Tunbridge Wells, Friday, July 2nd.

Brockham Rose Association, at Dorking, Saturday, July 3rd.

Eltham Rose and Horticultural Society, at Eltham, Saturday, July 3rd.

Crystal Palace Rose Show, Saturday, July 3rd.

National Rose Society, at South Kensington, Tuesday, July 6th.

Cardiff Rose Society, at Cardiff, Wednesday, July 7th.

Sutton Amateur Rose Society, at Sutton, Wednesday, July 7th.

Oxford Rose Show, Wednesday, July 7th.

Ealing, Acton, and Hanwell Horticultural Society, at Ealing, Wednesday, July 7th.

Bath Floral Fête and Band Committee, at Bath, Thursday, July 8th.

Ipswich and East of England Horticultural Society, at Ipswich, Thursday, July 8th.

Hitchin Rose Society, at Hitchin, Thursday, July 8th.

### FRUIT FORCING.

FIGS.—*Second Crops*.—Fruits in early houses have now swelled to a good size, and if judiciously thinned there will be a crop of fine Figs. This, however, depends upon their not being overcropped, the foliage being kept free from insects, and liberal feeding. If the crop is heavy, the former thinning not having been sufficient, a second thinning should take place at once, leaving the most forward at the base of the shoots, which will ripen earlier than the others, and so afford more time for the ripening of the growths. Early-forced planted-out trees should have the young growths ripened and be resting by the middle of October.

*Watering*.—If the borders were allowed to get dry when the first crop of fruit is ripening, they must be watered repeatedly through a mulching of a stimulating kind until the soil is thoroughly moistened down to the drainage. Liquid manure will be required by trees having their roots in borders of limited extent, and more frequently than by trees with a larger extent of rooting area; about once a week in the first case, and every fortnight in the other, giving thorough supplies, and always in a tepid state. The mulching should be kept wet so as to encourage surface roots.

*Insects*.—Syringing will need to be practised twice daily, except in

dull wet weather, when the trees will require to be syringed so that the foliage gets dry before night. Forceful springings are usually sufficient to keep red spider in check, but if it get a footing it must be dislodged of taken in time there is no better plan than syringing the leaves with a soft-soap solution, 3 ozs. to the gallon, and scale may be removed from the wood by using a brush. Painting the pipes with sulphur is an effectual remedy. The pipes should be heated to over 160°, and whilst hot painted with sulphur brought to the consistency of cream with skim milk. The house should be closed, the foliage dry, and the pipes kept hot for an hour at least after the sulphur is applied. They should then be allowed to gradually cool, syringing forcibly the following morning.

**Temperature and Ventilation.**—Artificial heat will not now be necessary unless the weather is unusually cold and wet, then fire heat will be necessary to maintain a night temperature of 60° to 65°, and 70° to 75° by day. Ventilate early, especially on bright mornings. Keep through the day at 80° to 85° with sun, and close sufficiently early to run up to 85° or 90°, or even 95°, providing plenty of atmospheric moisture.

**Succession Houses.**—**Fruit Ripening.**—With the fruit changing colour afford more air, insuring a circulation constantly, and a free movement of the atmosphere, by top and bottom ventilation, whenever circumstances allow. Gradually reduce the moisture, keeping it from the fruit, and exposing the fruit as much as possible to the full influence of light and air. A well-ripened Fig is delicious, whilst a badly ripened one is the most insipid of fruits. Lessened supplies of water will be needed at the roots, but they must not be allowed to suffer, therefore keep the soil moist, and the surface should be occasionally damped, indeed, it must be kept moist so as to preserve the surface roots. In order to keep down red spider, a thorough washing may be given the trees after the fruit has been closely gathered, and this repeated each time the fruit is gathered will keep the insects under until the crop is gathered, when more radical means can be employed for its eradication. If done sufficiently early on a fine day the fruit will not be in the least deteriorated, but the water must be soft, clear, and tepid.

**Trees Swelling their Crops.**—Mulch the borders with short manure 2 or 3 inches thick. Water through the mulching with tepid water, and in the case of trees carrying heavy crops and not having a tendency to over-luxuriance with liquid manure. It is hardly possible to over-feed Figs in well drained, properly constituted borders, and with the roots confined to limited areas. Wide, deep borders of rich material are great evils, and very unsatisfactory in results. The trees grow beautifully, but that is the extent of their utility. Syringe twice a day in fine weather, and always in good time in the afternoon, closing the house at the same time, and so as to gain enough sun heat to rise up to 90° or 95°. As the fruit approaches ripening admit a little air at the top of the house before night-fall. The grand secret of avoiding scorched leaves and scalds of all sorts is early rising, early ventilation—moisture deposited through the night dissipated by the rising sun. Evaporation, elaboration, and assimilation should always be sought in the day by commencing ventilation early, increasing with the sun's power, and growth sought by staying evaporation and restoring the wasted energies of the plants by a genial atmosphere, which is best effected in the early part of the closing day by sun heat and a moist atmosphere. This insures rest at night, the temperature being allowed to fall to a safe minimum.

**Late Houses.**—Figs are not so much grown in cool houses as they deserve. The fruit is of the most wholesome kind, and they make a grand addition to desserts. Narrow borders of calcareous soil well drained, and a light well ventilated structure, afford excellent results. The chief things are to grow thin, feed highly, ventilate early, and utilise sun heat by early closing. Keep the growths thin, stop at the fifth leaf—i.e., side growths, and keep the borders well mulched and watered. The trees will ripen one full crop in August, after which it is advisable to let the shoots grow up to the glass so as to get the young growths well ripened.

**MELONS.**—**Houses and Pits Cleared of Fruit.**—Prompt decision must be made as to whether the plants are worth keeping for a second crop. If the plants are healthy, and not infested with red spider, they may be reserved for a second crop, in which case growths should have been retained and encouraged in the latter stages of the first crop, and a good set will have been secured in these whilst the structures were kept drier for the fruit ripening. The old growths in this case should be cut away, but not all at once, as that would give a check, reserving the best of the growths, and any cuts that bleed should be dried with quicklime. Remove a little of the surface soil, and supply a malleable loam. Soak with tepid water, and follow at once with tepid liquid manure. Mulch with short manure collected, spread in a shed, and turned over two or three times before using as a mulch for the Melons, and are best given a little and often, rather than a heavy mulching all at once. If kept moist the roots will soon spread in the loam. Thin the fruits to half a dozen, or apportion the number to the vigour of the plants; but as the fruit does not attain to so large a size as the first crop, and as this will be the last crop off the plants, more fruits may be taken than is advisable for the first, especially when a second from the same plants is desired. Allow a fair extension of fresh growth, especially if the plants have to be grown on before fruit can be had, as not all varieties are amenable to the continuous system of cropping, and in that case it will be necessary to secure a good growth, and then seek a good set by a drier atmosphere.

**Replanting in Houses, Pits, and Frames.**—If the plants are not in condition for carrying a second crop clear them out at once, removing the soil, and the heat being had from fermenting materials remove a portion of it and add some fresh, mixing it with the fresher of the old, which will revive the bottom heat sufficiently for young plants. Cleanse the

house or structure thoroughly, much success depends on a good start. Plant on hillocks or ridges, or a couple of barrowloads of soil will grow a large plant, and it saves much trouble afterwards. Ram the soil firm, and when warm plant the Melons. Shade from bright sun for a few days, and maintain a moist atmosphere, but ventilate freely.

**Plants Setting Fruit.**—Artificial ventilation is not so essential now as early in the season. Insects of various kinds visit the flowers, and although humble bees and hive bees make most of the staminate flowers, they make mistakes and enter the pistillate and so effect fertilisation, rendering varieties of Melons very sportive and as plentiful as Blackberries in autumn. If, as there sometimes is, a difficulty in getting Melons to set in frames, apply good linings, and admit air freely, ventilating a little at night, so as to prevent the deposition of moisture on the blossoms, as to set the pollen must be dry and the stigmas not destroyed by moisture. Keep the foliage fairly thin, but it is not advisable to use the knife much during setting; still, light and air is essential. Avoid giving water if it can be helped, yet the foliage must not flag.

**Plants Swelling their Crops.**—Add fresh soil to the ridges or hillocks as necessary. Syringe plants in houses at closing time, and damp well down in the morning, and in the evening of hot days. Afford liquid manure copiously, always weak and tepid. Afford supports to the fruit in good time, placing slates under those in pits or frames. Keep the foliage fairly thin, avoiding too distant trimming, as allowing a large amount of foliage to be made and afterwards have to reduce it in quantity gives a serious check, and prolific of gangrene or gumming. Ventilate early or at 75°, keep through the day at 80° to 90° as sun avails, and close so as to run up to 95° or even 100°, with plenty of atmospheric moisture. A little ventilation about 6 p.m. will allow the temperature to fall gradually, any vitiated air escaping. As the fruit approaches ripening reduce the water at the roots, but not to flagging, and admit a little air constantly, withholding water from the fruit. Cracked fruits are mostly a consequence of a moist atmosphere at night.

#### PLANT HOUSES.

**Stephanotis floribunda.**—How frequently these are condemned as being non-flowering varieties when the fault is entirely due to the system of culture that is practised. Those that have failed to flower in the past may be turned into the most profuse flowering plants if the proper treatment be given. To flower *Stephanotis* abundantly it must not be grown in a close, moist, too warm, shaded atmosphere. Under these circumstances it will grow, but certainly fail to flower. If the resting and winter treatment has been right, and the plant is afterwards grown with its shoots trained close to the glass, fully exposed to the sun, and air when the weather is warm admitted daily, large trusses of flowers from every point of the wood are certain. Old wood well ripened will flower freely, but for a long succession of bloom the young growing shoots have to be relied upon. All who have plants in shady moist positions should expose them at once to the sun, and they will be certain, before the season closes, to have a good quantity of bloom from the young wood made very shortly after exposure. During bright hot weather air should be freely admitted, and light shade for two or three hours on hot days will be beneficial rather than otherwise, but, if this cannot be judiciously done without overshadowing, it had much better be dispensed with. It is unnecessary as far as the plant is concerned, but it assists in the preservation of the bloom. If the plant grown is confined at the roots it must be liberally fed with stimulants to encourage growth, for without fresh growth the supply of flowers soon fails. A good mulching of decayed manure on the surface of the soil will prove very serviceable, and the roots will quickly take possession of it. Artificial manures applied to the surface are also good, in fact this is the only form of feeding we practise. It is a great mistake to suppose that this plant will only flower freely when confined in a pot or box and thoroughly crammed with roots. When properly grown as regards light, air, and a moderately dry atmosphere, it will flower most profusely with considerable liberty at its roots. The *Stephanotis*, when the flowers are required for cutting, should always be grown where it is possible to syringe freely twice daily. If the plant is clean to commence with, it can easily be kept free from bug by this method.

**Tabernaemontanas.**—With the flowers of these plants there are generally produced numbers of young growths, which in a large measure hide the flowers. This is not the only drawback, for these growths rob the flowers very much. This can be prevented by their removal as soon as the flower buds are visible and growths are sufficiently large to be picked off. Fine large flowers are the result of this practice, and they open together much better than when the growths are allowed to come away naturally. There need be no fear of injury to the plants by this treatment, for they are certain to break back, and invariably produce more growths than if the first ones that started away had been allowed to remain. Young plants are of great value for various forms of decoration when subjected to this treatment. They can be grown into bushy little specimens, which flower as freely as plants of a larger size. When plants have ceased flowering they may be pushed rapidly into growth and assisted by the aid of liquid or artificial manure to the surface if confined at their root.

**Leoras.**—Plants of a young vigorous nature as they cease flowering should have their strongest shoots tied out, and the remainder cut back according to their length. If pushed again into growth in a moist close warm atmosphere they will soon commence rapid growth, which if ripened as made by exposure to the sun and air they will flower freely again in due time. Young plants make stronger and much longer growth than old ones that have become woody and somewhat stunted. They

should therefore be confined at their roots and fully exposed, so that they will produce firm sturdy growths which will bear large trusses of flowers. Any growing shoots that may be removed in pruning should be inserted singly in small thumb pots in sandy soil, and plunged in the propagating frame until they are rooted. These, if placed in 3 or 4-inch pots and grown on until they come into flower, will be found invaluable for decoration. Few plants equal *Ixoras* if grown under the influence of plenty of light and allowed to flower in from 3 to 6-inch pots, with from one to four or five shoots. If it is necessary to grow the plants on to a large size as quickly as possible, it is a mistake to allow them to flower. They should be given plenty of root room, and the shoots be pinched from time to time to induce them to branch, and the stronger ones from taking the lead.

*Pavonia Wioti*.—Very few of these plants are of any horticultural value, but the one under notice we obtained last year from Belgium, and it is a truly handsome plant, and worth a place in every stove however limited the collection. For decoration in small pots for front lines of the stove we do not as yet know its equal. It is valuable because its flowering period appears to extend over the greater portion of the year. After one set of flowers fade a few leaves are produced, and then the plant is quickly in full bloom again. If the plant is allowed to grow and flower a long time must elapse before a stock can be raised. The flowers must be removed and the plant forced to make growth if cuttings are to be obtained, the cuttings even persist in flowering. Cuttings are easily rooted in any sandy light soil if inserted singly and plunged in the propagating frame or placed under a bellglass.

## THE BEE-KEEPER.

### INITIATORY INSTRUCTIONS.—No. 4.

A most important time with bee-keepers, and the proper time to prepare hives for the moors or for the subsequent season, is just at the close of the Clover harvest, occurring between the middle and the end of July. The best results will follow in either case by substituting young for all old queens, or those which have done service for twelve months previously. The young fertile mothers which are now to supersede the aged ones ought to be in nuclei and breeding, having been transferred from a strong stock about eight or nine days after its queen had been removed, say a month or more before the anticipated close of the honey season.

These nuclei may be divided as circumstances will admit or the fancy dictate, but six are not too many to form from a strong stock. I am usually successful by making a dozen from one strong stock in a frame hive. One comb containing a royal cell with bees adhering placed between sheets of foundation into a hive capable of holding twelve or more frames, with perfectly close-fitting dividing boards between every three frames, makes four in the one hive, mutually keep each other comfortable; and when there is an entrance at each side, as there should be, there is no possibility of any of the bees or queen making a mistake. Moreover, this plan gives facilities for removing many nuclei a distance for pure fertilisation and at little expense. The outside combs containing much honey, with an excised royal cell inserted wedge-shaped, with but few bees, should be placed near the old site, so as to catch and distribute the flying bees regularly over these combs. The above refers in a great degree to square frame or bar hives. The bee-keeper, however, will from the instructions given understand how to manipulate the octagon Stewarton to obtain satisfactory results. In all cases of introducing young queens it is advisable to cage them sometimes in the immediate vicinity of the bees deprived of their queen before introducing. The queen runs less risk of being killed if introduced singly with any bees, but I do not like to lose the bees that formed the nucleus. To preserve them, and lessen the risk of losing the queen, I had a cage of fine-meshed wirecloth of the proper size to hold two frames, having a slide door on one side and a cover for the top. Immediately after the queen was deposited I put the nucleus with its queen in the cage, and when all the bees had entered I closed it. The moment I observe the bees of the queenless hive show symptoms of the loss of their queen by their excited and frenzied commotion in front of their hive, I insert the cage containing the nucleus in the

centre of queenless hive. If they immediately become quiet and cling loosely to the cage it may be reckoned safe to let the two lots join by drawing the sliding door. Next day the cage may be removed. With the young queen breeding will be carried on briskly, and be in a capital state as a honey-producer at the Heather or for wintering and coming out in spring a strong and profitable hive. Provided it had sufficient natural stores at the beginning of August, or if not had been fed at the above date with not less than 30 lbs. of best sugar made into a proper syrup, with as much water when dissolved and boiled a minute as will form a rich syrup.

Feeding, however, is in every form an evil unless when it cannot be avoided. It is desirable bee-keepers should become impressed with the fact. It is the first duty of bee-keepers, when once in possession of bees, to take care of them. Now, feeding, particularly in the autumn, causes bees to attack others or induces the unfed bees to attack the fed ones. In both cases bees are killed or lost, not only by that, but by the tear and wear of their bodies consequent on the excitement they are unwisely put into by the injudiciousness of the bee-keeper. Then, although none may be actually killed, the queens in many cases will meet with an untimely end from the stranger bees entering the hives as robbers. It is the instinct of bees to kill the queen when they attack the hive. The best and safest time to feed is at night at the close of the honey season. Then covered with thoroughly dried long grass about 5 inches deep on the crown, and slightly on the sides if the hives are single-cased, defend from rain, contract the entrances, and ventilate beneath by ventilating floor; it does not require to be opened—the vacant space is sufficient. Press the grass firm to the top and have the slides drawn. The hives so prepared require nothing more, and need scarcely be looked at until spring, when the bee keeper in search of pleasure finds enjoyment in the bees rifling the unfolding favourite flowers of their nectar and pollen, returning to their hives with their equal-loaded thighs of varied hue, gathered and packed by assiduous labour, but to them a pleasure and happy life.

To find the queen some people are at first at a loss how to detect her amongst the busy throng. All intending bee-keepers should procure one or more queens, and thereby become acquainted with their appearance, and be able to detect the queen when examining the frames, or if of necessity from driven ones or a swarm. But in the majority of instances, where a case open at both ends and of the same diameter of the hive is placed underneath a stock of bees, and having one end an inch or two down filled with excluder zinc, the bees, on being driven from their hive with carbolic paper, will pass through the zinc, but the queen will be found above. The above plan with strong stocks of bees is perhaps the safest and easiest plan of catching a queen.

Hives properly managed up till the end of the Clover harvest should not require any strengthening by joining other bees to them. Those not going to the Heather, but with a young queen added, should by the youthful element produced be all that can be desired, and should be left undisturbed as already advised; but with those going to the Heather, if the young bees are not likely to be hatched in time to be profitable by carrying in the honey, stocks should be doubled or trebled. From the time an egg is laid till the bee is hatched and able to work outside five weeks must elapse. Intending bee-keepers should keep that in mind, because upon the number of adult bees in the hive and the forwardness of the brood depends entirely the amount of honey that will be collected. A young fertile queen introduced to a strong swarm six or seven weeks before the honey glut will give good results, but eight or nine weeks will give extra results, and less than the first-named will be of little use, so where that cannot be managed strengthen the stocks by joining several together. If such hives have a young fertile queen the hive will be quickly filled with brood, and when the honey glut comes the supers will be filled rapidly with what in the absence of a young

queen would have been stored in the body of the hive. By following these directions the delicate super comb is obtained, and the hive is at the same time, by extra breeding, being put into the best condition to stand unharmed the severest and most protracted winter that we have ever experienced in this country, and will be far ahead of those hives having had all the attention and nonsensical manipulations advised by inexperienced teachers, and will collect a much greater quantity of honey.

Smokers are sometimes useful in the apiary. Those giving a great volume of smoke are held in great repute by most bee-keepers; but smoke injures the bees and brood, taints the honey, and is disagreeable to the bee-keeper, so my desire is to banish it as much as possible from the apiary. I have seldom used a smoker, not for many years. Carbolic acid is preferable, and is beneficial to the hive if the bees are not smeared with it, being fatal to them if that is done. A little care in its use will prevent any casualty of that kind.

The foregoing instructions will be found useful both by bee-farmers and the bee-keeper proper. However, the former pursuing the art wholly from a commercial point of view, may perhaps lose patience and fail to adhere strictly to my instructions, thinking that it is impossible to manage bees with profit without adopting the notions which I have pointed out as being so detrimental to successful bee-keeping. Time, however, will convince them of their error. It is not, however, to them so much as it is to the latter class I have endeavoured to impart the information. The bee-farmer will insist that extracted honey is the most profitable. That depends entirely upon the price obtained for it. The main question at issue is the quality in the first place and quantity after. The rules I have laid down secure both with least labour and expense, insuring strong stocks at all times.

There has always been, and will always be, a great difference in the quality of honey. Honey thrown out by the centrifugal extractor is always thin, often so much so that it will not candy. Fermentation is sure to set in sooner or later, and then parts with all its qualities that constitutes good honey. Good samples of drift or pressed honey become solid and hard, but there is no extracted honey that has the delicious flavour that comb honey has. Honey being composed of different sugars and other substances which are required to form good honey, are also of different specific gravity; so that whenever honey is canned the proportions separate—the densest falls to the bottom and the lighter goes to the top. Thus the richness of the honey caused by the natural blend is destroyed. The honey must be retained in the thoroughly sealed combs. Any artificial process to ripen honey or mixing it with foreign ingredients destroys it. A mixture may be made to please certain palates, but no art will improve either it nor the industrious workers that gather it.—A LANARKSHIRE BEE KEEPER.

### INTRODUCING QUEENS.

It was my intention to have written a special article on queen introduction, but after the remarks by your correspondent "A Hallamshire Bee-keeper," at pages 475, 476, there remains but little for me to add, provided bee-keepers will bear in mind "That when bees are queenless, and have no means of rearing one—that is, have no eggs, unsealed brood, or queen cells in their hive, they will invariably accept a fertile queen at the flight hole, or dropped in from the top, provided they have been queenless for forty-eight hours," and may I add, no fertile worker present. All that is necessary for the bee-keeper to do is to remember the above and act accordingly.

There has, no doubt, been much nonsense written upon the introduction of queens direct and otherwise, which has rather baffled the bee-keeper than make the work plain and easy to understand. After bees have been queenless for months, and sometimes for only two days or so, I have caused the bees to follow me, and even enter my pocket after a queen I had presented to them in a cage and then withdrew it. There is no better sign than this that the bees will accept a queen directly if offered. It is when bees have eggs, larvae, queen, or royal cells containing what will emerge a queen in due course therefrom, or a fertile worker, that there is a difficulty in introducing a strange queen, or even a ripe queen cell to. Caging the alien queen then becomes necessary for the purposes of reconciling the bees to her, preventing the latter starting royal

cells, for if one is allowed to remain in the hive or be raised, in almost every case the introduced queen will be killed. Many queens are lost by being introduced when in an excited or frenzied state; when so the bees will ball her, or she will leave the hive and be lost. It is therefore desirable when introducing a queen to close the doorway, so that it is impossible for her to escape.

In addition to what is stated above, I make it a rule to depose the queen exactly eight days before I introduce an alien one. The only precaution required is to make sure that every queen cell commenced is destroyed. I then put the queen into my safety cage, and place it over the bees on the top of the hive. These cages are about 3 inches square and 1½ inch high, having an apartment for the queen, and another for the bees of the hive to come up and fraternise with the queen. A few minutes decide whether I should draw the little slide and let her free. This cage is, I consider, a great improvement upon what is termed the Benton cage. The latter, I may say, was used by me more than twenty years ago, and an acquaintance from the north of Scotland told me the other day he had still the one I sent him eight years ago. I only mention the fact in consequence of the *British Bee Journal* having spoken so highly of the Benton cage, which I quite agree with; and to prevent anyone thinking me guilty of the mean practice of appropriating others' ideas, so common amongst bee-keepers of the present day. In this instance I am rather proud to see the enterprising Benton hit on my own plan without having heard of it. The frame cage I mentioned lately as being similar to the one described by Mr. Blow, I use to preserve the bees forming the nucleus, not the queen. I hope these supplementary remarks to "A Hallamshire Bee-keeper" will be sufficient to guide any inexperienced amateur how to introduce queens successfully.

While on the queen question I observe the *British Bee-keeper's Record* says that bees often use the royal cells for raising queens, a thing I never have seen. It is against the nature of the queen to lay an egg in a queen cell, and it is yet to be proven that bees transfer eggs from worker to queen cells, or from one cell to another.

Mr. W. W. Young, Perth, asks me to do justice and put the matter right regarding who was the first to cause the bees to work ornamental designs. This request is due to the fact that Mr. A. MacNally, Glenluce, claims the invention, although only four or five years a bee-keeper. I would have preferred in this case to have seen the discussion carried out against the erring individual in the journal where it appeared. I cannot say who was the first to start ornamental designs in honeycomb, but I know that there appeared in this Journal many years ago a woodcut of an ornamental glass of honeycomb supplied by "A Renfrewshire Bee-keeper." Twenty-five years ago Mr. John Craig, Stewarton, carried out the system largely, and about the same time I tried my hand, and was very successful with some designs. But in justice to Mr. Young he exhibited at the Caledonian Apian Society's Show, held in Perth some six or seven years since, the arms of Perth, together with the motto in reading, prettily wrought out by the bees. It matters not to bee-keepers who the inventor of anything relating to the apiary is; but when persons claim the invention of anything not their own for mercenary purposes it is wrong, and ought, I think, to be corrected.

A case in point with myself is that of a dealer in supplies—viz., Mr. Abbott—claims to have won a silver medal for the best frame hive at the Kibble Show held in Glasgow by the Caledonian Apian Society in 1876. There were no silver medals awarded at that show. The first prize was awarded to my hive, not to Abbott's; but I agreed to the suggestion of the judges that as Abbott had come so far to the show to encourage him, would I agree, although first, to share the honours with him, to which I agreed. It would have been different, however, had Messrs. George Neighbour & Sons' exhibits been forwarded in time. The goods sent by that firm were too late in arriving to be judged.

At that same show I exhibited a sunshade attached to the hive, which for a hot season or climate was a decided improvement. Somebody before the judging thought it worth their while to lay down upon and break it. I showed it to one of the judges as best I could. A few weeks after the show, the Editor of the *British Bee Journal* said, "No one had as yet thought of shading hives." I have done so for forty years.—A LANARKSHIRE BEE-KEEPER.

### PLACING SWARMS INTO STEWARTON HIVE.

I HAVE a swarm of bees in a straw skep which I should like to transfer into a Stewarton hive or hives. I am not particular about increase of stock, but I wish to get the most honey possible this season. To insure this would it be best to place them into two hives as they swarm, and at the end of twenty-one days from issue of first, drive the old stock and unite it to one of them; or, at the end of fourteen days after a natural swarm, drive a second, and after twenty-one days drive all out, and put the whole together? The queen is two years old. If I put them all into one hive should I destroy the old queen, or chance the fittest to survive? And if I should destroy her what would be the best way to manage it? We have a long honey season here. The bees are working on the white Clover at present, and before it is quite past the Heather will be in bloom.—J. E.

[Place your first swarm into two Stewarton body boxes, fitted with comb foundation. In ten days after place on a super and cover well. Do not attempt to kill the old queen unless you have a fertile one to supersede her. As the queen is two years old, it is not unlikely that the first swarm may have a young queen. This occurs very often, and bee-keepers would be doing right if they never kept any but young queens. Place the second swarm into a single body box and the driven bees from the old

stock the same, and in three or four weeks add another box, and with a little feeding both should be in good order by the time the Heather is in bloom if the queens do not meet with any accident. If you wish to have a very strong one, three weeks after one of them is fertilised depose the old queen of the first swarm and add box, bees, and brood of one of the young queens to it. The old queen is thereby removed, and you will have two good stocks for this as well as next year. Never leave the queens to decide which is the fittest, unless both are young or *vice versa*.]

### TRADE CATALOGUES RECEIVED.

Ewing & Company, Sea View Nurseries, Havant, Hampshire.—*List of Roses, Ivies, and Hardy Climbing Plants.*

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**TO CORRESPONDENTS.**—We desire to assure those of our correspondents whose letters and communications are not promptly inserted that they are not the less appreciated on that account. Our pages are practically filled several days prior to publication, and letters arriving on Wednesday morning, except by special arrangement, are invariably too late for insertion. The delay in the publication of some of these is not of material importance, but reports of meetings and shows held a week previously lose much or all of their value if not received in time to appear in the current issue.

**Flower Shows (Ferndale).**—If you consult the "Coming Events" at the head of our leading article each week you will see the principal shows announced for the week of issue. We have also published a list of shows for several weeks, and you will find several advertised in the second page of the cover.

**Melons Failing (T.W.).**—We do not think the fault is in the soil, but the house is too damp considering the temperature that is maintained. Increase it from 5° to 10° at night, and the collapse of the plants will probably be arrested. We have seen many similar instances of plants failing in naturally damp houses, and a higher range of temperature has almost invariably proved beneficial.

**Propagating Double Gorse (Whin).**—Side shoots or slips of nearly ripe wood are inserted firmly in sand under handlights in a shaded position in summer and early autumn. They should be inserted two-thirds of their length and kept moist. You had better not expect that every cutting will strike, but put in plenty to allow for a few failures.

**Ammonia in Ferneries (D.).**—A solution of sulphate of ammonia sprinkled on the paths and stages in the evening is good for most plants, but we have not tried it for Ferns, as ours are as healthy as can be desired without having recourse to that practice. We should not apply it to the hot-water pipes at any time, nor to the paths in the daytime in bright weather, but only in the evening when closing the house.

**Peach Leaves Injured (G. M.).**—The leaves you have sent are not blistered, but the tissue has shrunk, dried, and fallen out in places. We have known this occur after strong fumigation, and as you have plants in the house you may possibly have been fumigating for the destruction of insects. If you have not we can only attribute the shrivelling of the foliage to excessive transpiration, or moisture passing from them more quickly than it is supplied by the roots, and in that case additional supplies of water must be given to the border.

**Plum Trees, &c., Infested with Aphides (E. D. Y.).**—The points of the shoots are infested with aphides. The best remedy is to summer-prune at once—i.e., cut off all the young shoots not required for extension and burn them. The shoots not removed should be dipped in tobacco water and rubbed with the fingers so as to wet the aphides. Tobacco juice diluted with a fourth or sixth of water is suitable. The trees should then be syringed with the tobacco water, six parts of water to one of tobacco juice, and follow in a day with softsoap solution, 2 ozs. to a gallon of water, and afterwards with clear water for a few evenings so as to thorough wash and clear the trees of the insects. The perforations have no doubt been caused by small green caterpillars. The only cure for them is hand-picking. They are usually found at the back of the leaves, or folded up in the leaves. Squeezing those between the finger and thumb is a ready means of

destruction. The active insect is no doubt "ladybirds" come to feed on the aphides.

**Apple Shoots Dying (J. H.).**—Your Apple trees have been attacked by a caterpillar, the larva of the small ermine moth, which is highly destructive. It may be destroyed by syringing the trees with a solution of softsoap, hellebore powder, and petroleum; but this ought to have been done sooner. That, however, is not the sole cause of the evil of which you complain, for the shoots sent are so weak and densely covered with moss and lichen that we suspect the roots have perished in wet soil. We doubt if such old trees can be renovated, and the only means we can suggest for improving them is to dig drains for conveying stagnant water from the soil, cut out all the dead portions after the leaves fall, and dust every twig when wet with newly slaked lime. Removing some of the old soil down to the roots, adding fresh and covering it with a thick layer of rich manure might also be of service in encouraging the extension of healthy roots near the surface of the ground.

**Glass for Vineries and Plant Houses (J. R.).**—You have failed to indicate the district from which you write. This is a rather important omission, because there is far more sun in some parts of the kingdom than others, and this has a distinct bearing on the case. We can only say that as a rule rough glass is not the best for Vines, and in some districts it would be decidedly inimical. We have known long ranges of vineries glazed with rough glass, but good Grapes could not be grown in them till the houses were reglazed with clear glass. The change from inferior to superior Grapes was not the result of a change of gardener, for the same person was in charge throughout, though he was not responsible for the selection of the glass in the first instance. Nor is rough glass suitable for hardwooded and flowering plants generally, except perhaps Camellias; but Ferns and ornamental-foliaged plants flourish very well under roofs of the nature indicated. You had better show our reply to your employer, and consider the whole matter well before deciding on using rough glass for vineries. We dare venture to say that not one prize will be awarded at Liverpool next week for Grapes that have been produced in houses glazed in the manner advised by your architect.

**Prizes for Wild Flowers (Wilfrid).**—You ask:—"Are annual prizes of small amounts (say from 5s. to 2s. 6d.) for the best collection of wild flowers of the district at a local flower show of benefit in the interest of botanical science or not? Do not a continued search for such collections gradually exterminate many a rare plant from the district flora? Which is best, an annual collection or a carefully preserved collection, duly named and classified, and prizes offered for the best collection of plants that are not to be found in this preserved collection?" Undoubtedly a carefully preserved, duly named, and classified collection is desirable for educational purposes, but we are inclined to think that offering prizes for plants only that are not in that collection would be more likely to lead to the extermination of "rare" species from the district flora than would result from the alternative plan of offering prizes annually for fresh collections. We fail to see that the methods can be properly placed in comparison, and we are of opinion that the adoption of both would be better than the exclusion of either. Wild plants are not exterminated by gathering flowers from them, but by digging up the roots. Cutting off all the leaves would weaken the plants, but it is not usual for this to be done in cutting the flowers. Let it be an injunction that flowers only are to be cut, with such leaves that grow on their stems, the roots not to be disturbed at all, and a love for native plants would be inculcated, and collectors of flowers become preservers of rare species. We have not the slightest objection, however, to publish any opinions that may differ from our own on this subject. It would be a very good plan to preserve any flowers exhibited that are not included in the dried collection, and this would then be gradually extended.

**Vine Leaves Scorched (F. G.).**—The cause of the withered condition of the leaves we attribute to defective ventilation, due provision not having been afforded for the exit of dry heated air, and this has encouraged the increase of the small insect, but great Vine pest, the red spider. There is no "cure" for such leaves as those you have sent, but the evil may be prevented from spreading to the others with better management. At no time should the top ventilators be closed entirely, except for an hour or two after syringing or damping the house in the afternoon, opening the top ventilators an inch or so at nightfall, and increasing the openings immediately the temperature commences rising in the morning. Carefully remove the worst leaves and burn them, and you will destroy many insects that you will not see. Syringe the Vines as violently as you can short of injuring the leaves. A mere squirting will be of no use, but point the syringe between the bunches and drive the water directly to the under side of every leaf, thus giving each a thorough washing. If this work is done thoroughly not many insects will be left on the foliage. Use a gallon of water to each square foot of roof, more rather than less. One good washing of this kind weekly will be more effectual than daily sprinklings. This washing should be done soon enough in the evening for the Vines to get nearly dry before night. Syringe every part of the house well every evening in sunny weather; let not a dry spot remain of soil, walls, or woodwork; also immediately after the sun has left the house, and the Grapes stoned, sprinkle the paths well with liquid manure. Guano water will do admirably, 2 ozs. of the fertiliser being dissolved in a gallon of water; but take care to open the top ventilators three or four hours afterwards, as above advised, leave them open all night, and give more air as early in the morning as is required, even if this be at five o'clock, the time depending on the position of the house for receiving the morning sun. Water the roots of your Vines copiously if the soil is in the least dry, not on the surface only, but 2 feet below it. If you carry out these instructions as we should act on them ourselves, your Vines will improve. Late syringing may be done in sultry weather, not on cold wet nights. It is much better to shade Vines lightly than to let the leaves and berries be scorched, as yours are. If your Vines are overcropped remove some of the bunches.

**Feeding Vines Through the Foliage (Omega).**—Supplying ammonia in the atmosphere of vineries has long been practised, certainly more than half a century, and has been frequently referred to in the *Journal of Horticulture*, especially in "Work for the Week." It is best afforded in the

early stages by beds of fermenting materials made up inside the house, and turned over frequently so as to prevent over-heating, and when the heat is declining adding fresh. The ammonia is also liberated more freely when the material is open than when closely packed. During growth light mulchings of fresh droppings are the best to afford ammonia, giving a light sprinkling about once a week, and continuing it up to the time the Grapes change colour. The droppings will get damped frequently, and give out ammonia with the moisture. Care should be taken not to give too much. Liquid manure—that from stable and farmyard cesspools, sprinkled on the pathways in the afternoon at closing time is beneficial. We use a four-gallon watering pot full in a house 40 feet by 20 feet, and through a rose. The best is the drainage from stables, it smells sweetest, and is mostly urine. This we dilute with six times the quantity of water, and apply through a rose watering pot fresh about 5.30 P.M., giving sufficient to damp all available surfaces, and we always ventilate fruit houses before nightfall. In a close atmosphere with sun ammonia does harm, often great injury, and it must be used with care. In vineries commence when the Vines are started, and do not discontinue it until the Grapes change colour.

**Fairy Rings on Lawn (Old Subscriber).**—The appearance of these rings has been thus described by Mr. Worthington G. Smith:—"Fairy rings, as formed by Agarics, probably start from a single Fungus which has grown from wind-carried spores. The growth of the spawn of this single Fungus in the ground renders the spot where the individual grew unfit to produce another Fungus of the same class. The spawn then extends itself from the central spot, and grows all through the winter and following summer a circular patch in the earth. One year's growth will give a circle of about 6 inches, and on the outside of this little circle a small fairy ring of Fungi will appear the second year. When this ring of Fungi dies it acts as a rich nitrogenous manure for the grass, so that in the third summer a circle of rank fungus-manured grass is seen. The grassy circle is often in strong contrast with adjoining dead grass killed by the Fungus spawn infesting

Fig. 95.—Fairy Ring. The ground partly shown in section, A centre, where the original Fungus has decayed, and whence springs the underground spawn, B. B, of the Fungus (*Marasmius oreades*), which gives rise to the fairy ring.

the roots. If circumstances are favourable the underground spawn will now keep on extending itself for forty years or more, until at last an enormous circle is made that may sometimes be seen on hillsides from a distance of a mile or more. If an obstruction occurs a semicircle may sometimes result; at other times, when numerous rings grow near each other in the same pasture, or on the same hillside, various ogee curves and wavy lines of rank grass, barren ground, and Fungi are originated. Sometimes a large fairy ring will appear in a place, as on a lawn, where no Fungi have been seen before, and where no smaller rings have preceded the large one. This phenomenon is caused by the first Fungus being overlooked, and then a series of seasons have followed unsuitable for the production of the Fungi. The spawn, however, has been alive underground, and has kept on year after year extending itself till at last a suitable season arrives, and a crop of Agarics is the result at the circular margin of the underground spawn."

**Destroying the Fungi (Idem).**—You will do no good by digging up the circles, but as the rings are a great disfigurement make holes with a crowbar so as to open the soil beneath the grass, and about a foot deep, and fill them with liquid manure from a tank receiving the drainings of stable, cow-byres, &c., soaking thoroughly twice a day for a week. Potash and nitrogenous manures are needed to eradicate fairy rings. Apply manure, animal or vegetable, or decayed farmyard manure, or the debris of rubbish heaps reduced to mould. Compost formed of ditch cleanings, &c., with a load of lime to every six or ten of the other, thrown in a heap, now or in late summer, and turned over a time or two will be fit to apply in February. A good manuring may be given at that time, or not later than March; but the compost will not give so rank a growth of grass.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*Subscriber*).—We do not undertake to name more than six specimens at one time. 5, *Lonicera sempervirens*; 7, *Begonia metallica*; 9, *Begonia lucida*; 10, *Acalypha Macafeana*; 11, *Pteris serrulata*; 12, *Tradescantia discolor*. (*Somerset*).—2, *Carex acuta*; 7, *C. flava*; 8, *C. pallescens*; 9, *C. ovalis*; 10, *C. riparia*. (*J. C. H.*).—4, *Ribes speciosum*; 5, *Chelidonium majus*; 6, *Anthericum liliastrum*. The others were too much withered to be recognised. (*Herbert Fleet*).—1, Paul's double Scarlet Thorn; 2, *Cratægus coccinea*; 3, *Cratægus ovalifolia*; 4, *Pavia flava*; 5, *Cornus sanguinea*; 6, *Berberis vulgaris*. (*A. K. C.*).—*Calanthe veratrifolia*. (*Cheshire*).—*Crinum capense*.

GREEN PASTURES.

SPECULATIVE farming if carried on so extensively as to involve risk of loss is a serious matter. It is a rash proceeding on the part of anyone, and is especially to be avoided by the home farmer, whose position of high trust should render him doubly cautious in what he undertakes. It may undoubtedly be said that all farming operations are more or less of a speculative nature, from the fact of results being so dependant upon weather. That, however, is well understood, and due allowance is made for it; but the term speculative is used here to indicate novel cultivation, a bold step out of the beaten track, a venture of such an experimental character that the result may prove a total failure. Yet without experiments

how is improvement possible? Certainly we should try experiments—every farmer should do so for himself, but it should invariably be done on so small a scale that there can be no material loss. We would have on every farm of a hundred acres and upwards a few perches of land set aside for trial plots. In our own practice we like the plots to be a series of parallelograms, 12 feet by 6 feet, with narrow paths between, and a broad path along the front. This plan enables us to test seed and manure under precisely similar conditions, and we derive much pleasure and instruction from it. When we first began our trials we were told that such little plots of corn would certainly attract the birds and we should lose all the grain as it ripened, but we sustained no such loss, and we gained much useful information from our trials of all the sorts of Wheat, Barley, and Oats procurable, and sown side by side. Roots and green crops were also tried in the same manner.

Of green crops the Grasses and Clovers were the most important, our object being to ascertain the value of certain sorts either for temporary or permanent pastures. It was found that the best way of doing this was to sow one plot of each sort, and to sow two or three plots with different mixtures. By this means much useful information was obtained of the relative value of the sorts tried as forage plants, and this is also one of the best ways of becoming familiar with them. It is by no means intended to assert that one can learn all about Grasses in this way, far from it, but by intelligent observation and by reading all that is written about them, a fund of useful information may be gained upon which to draw in the actual process of laying down land, especially in permanent pasture.

Simple as is the process of the sowing and development of new pastures, there is probably nothing in agriculture so badly done or which so frequently proves a failure. We were recently asked in "The Land Agents' Record," to "Look at the newly laid pastures which so often fail, in which the strong and robust Grasses stand alone, and the finer ones either do not come up at all or die off as soon as up. The seed is blamed, the season is blamed, the birds are blamed, but the real cause is too often (not always) the want of tilth. Careful husbandry can alone secure this, and a careful sowing to cover every seed, and this not too deep. When walking lately over a young pasture, the result of surface sowing, the uncovered seed was apparent, the plants were living a struggling existence—sitting, as it were, upon the surface." We happen to have seen a similar example of slovenly husbandry this season, a poor tilth, the soil quite hard in some places, and the seed scattered upon the surface by hand. Much of it appeared to be growing, but many of the finer Grasses will be lost in July. If we would have green pastures worthy of the comprehensive designation, we must set about it in the right way, and work out the entire process step by step. To be really master of the work there must be no omission of a single detail from trial plot to well-knit pasture. Repeatedly have we enumerated every detail of the work:—Soil well drained, made clean of foul weeds so far as roots are concerned, so broken up by plough cultivators, harrows, rollers, and horse hoes as to ensure a deep very fine tilth, and sufficiently stored with fertility to induce a free strong growth from the beginning; most careful management for the first two seasons, preferably by lamb-folding the first year, and sheep-folding in the second. Can anything be more simple, and apparently more easy?

Before writing this paper we had been over some 200 acres of grass land laid in for hay. Out of that rather large area even for a home farm we found only about one-fourth had a really full crop, the remainder having in some places half a crop, and in others there was hardly enough grass to mow. The cause and remedy were not difficult to understand. All the faults in the crop were clearly owing to faults of soil and not of season. Poverty and a want of drainage were the chief evils, but there were such others also as usually follow carelessness or mismanagement in laying down land to

pasture. How bitter must be the feelings of the owner of such pasture if he has sufficient knowledge or sense to know that his property is spoilt, his means wasted through mismanagement. Crass ignorance and its invariable concomitant of conceit may be passed by with a smile of pity, a feeling of regret, when displayed by a tenant farmer, but a home farmer who is found wanting in practical knowledge of his calling must know that he will have to suffer for it. Repeatedly have we had to listen to positive statements that a growth of "natural" Grasses makes the best pasture, and while refraining from the very natural desire to answer a fool according to his folly in the double meaning of the term, a leading question or two makes him tell one that such men eschew trial plots, and are ignorant of most of the details which go to the management of Grass land so as to render it worthy of our title of Green Pastures.

#### WORK ON THE HOME FARM.

Though continued much later than usual corn-hoeing is now over, the last job of this kind being a second turn after Thistles among spring Oats, and the men were then sent with the hoes among the Mangolds, both to get weeds under and to thin the Mangold plants which are now making rapid progress. With the exception of one heavy land farm where the plant is thin and weak, the Mangold crop bids fair to be a good one, although backward in comparison with the growth of ordinary seasons. We have several trials of various manure mixtures for Mangolds in progress, concerning which we hope to have something to say in due course. Swede seed germination has been satisfactory, and it was followed by a growth so quick as to soon place them out of danger from the ravages of the Turnip fly. The first sowings of White Turnips are making satisfactory progress, our especial object with this crop being the early folding of old sheep. As the sheep clear off the crop of Winter Tares the land will be ploughed in readiness for drilling cattle Cabbage in July, for a supply of green food for sheep or cows late next spring and in early summer. The haymaking which began with Sainfoin followed by Red Clover, Rye Grass, and mixed layers, will now soon become general among meadow Grass also. The purchase of a couple of new rick cloths is a reminder of occasional negligence to provide such means of protection for hayricks during the haymaking. Yet to undertake haymaking without rick cloths is indeed a rash proceeding. Nor is it enough simply to cover the rick with a cloth, for there is a right and a wrong way of doing this. The right way is to raise and lower the cloth by means of three poles—two being set upright at the ends of the rick to support the third pole, over which the cloth is thrown to be raised and lowered by ropes in pulley blocks fastened near the tops of the upright poles. Although arranged to keep off rain from the rick in course of construction, the cloth is kept far enough above it to allow the vapour arising from fermentation to escape freely. We allow no ricks to be in actual contact with the soil, but have a double layer of spray faggots at bottom. Negligence of this simple matter often causes much hay to be spoilt, for when the hay is pressed down upon the soil moisture ascends by capillary attraction, and a layer of considerable thickness becomes musty and worthless. We prefer making a few big ricks to having several small ones. A rick which at bottom measures 12 yards long by 6 yards wide may be made so as to contain from twenty to twenty-five tons of hay, which if well made and put in the rick with due care is quite certain to prove really excellent food. For ricks of this size a sack stuffed with straw should always be drawn upwards at the centre of the rick in the building to form a funnel for the escape of vapour.

#### METEOROLOGICAL OBSERVATIONS.

#### REMARKS.

13th.—Generally bright, with one or two slight showers.  
14th.—Fine bright morning, cloudy afternoon, with slight rain towards evening.  
15th.—Cloud and sunshine, the latter predominating in the afternoon.  
16th.—Generally cloudy, but some sun in early afternoon.  
17th.—Fine, but not much sun.  
18th.—Cloudy, and very cold.  
19th.—Rain very early, cloudy morning, with occasional slight rain; fine afternoon, cloudy evening.  
A dry week, but cold and quite unlike June. Day temperatures several degrees below the averages, nights not relatively so cold, as the clouds have prevented radiation.—G. J. SIMONS.
